The first is the "Workers' Estimate of Unemployment Insurance." He tells us that, almost without exception they are in favour of some form of insurance, but have "complete lack of confidence in the exchanges as placing agencies." "Without question, the most severe criticism of unemployment insurance, favourable and unfavourable, came from the workers themselves. Their understanding of the situation was based on first-hand experience." The second heading is "Effects of Unemployment Insurance," and must be taken with the third, which is "Security *versus* Fear." In the first, Dr. Bakke rapidly sketches the manifest advantages of unemployment insurance, but observes that "it has not relieved and cannot by its very nature relieve the mental and moral fatigue and discouragement which result from having no job. It cannot supply the loss of status and the sense of self-respect which vanish with the job." Yet it saves them from utter degradation. "The sum, small as it is, . . . means the difference between giving up and keeping on as a self-respecting individual." In the second of the two sections named, Dr. Bakke challenges the view of those who aver that a constant fear of being down and out is a spur to endeavour. "In cases where fear would not be demoralising," he says, "it is not necessary or useful. In cases where it might be supposed to be useful or necessary, it is demoralising." He writes from a warm heart on this subject, but we doubt if it can be easily dismissed. It is not only in the working classes that a fear of being "down and out" exists. It is just as strong in other classes of society, and there can be little doubt that, on the whole, it has a stabilising influence which is generally for the good. When the security of the "dole"—we use the word only because of its convenience—tempts men to throw up jobs they have, or at any rate not endeavour to retain them, it is misused. One of the great troubles with unemployment insurance is that it falls alike upon the worthy and the unworthy. How to preserve its merits so that it has all the good effects upon which our author dwells, and to get rid of its defects, is a problem which so far economists and humanitarians have failed to solve completely.

This brings us to the next division of Dr. Bakke's conclusion, "Effect on Willingness to Work." Here he writes: "A great deal of confusion is caused by the application by one group of society of its own standards to the behaviour of a different group." The middle-class man has no right to assume that the incentives which actuate him will also actuate a working-class man. "Comparatively speaking, the group from which this man [the workman] came never possessed the degree of incentive assumed by middle-class individuals to be present. . . . The practical control of the worker's destiny from beyond himself and his own group has left him with a minimum of responsibility for his own fate and the feeling that it is up to the masters to do something about it." We are afraid that there is a good deal of truth in that statement. And we are still more afraid that the emotion which it records is spreading upwards. If the workman expects his employer "to do something about it," the middle-class man is now given to demanding that "the State should do something about it." In neither sphere of society is it an attitude which should be encouraged. Dr. Bakke's observation, drawn from life, is no doubt accurate, but, we would ask him, Ought not every effort to be made to resuscitate or to generate a feeling of independent responsibility in the working, as in all classes of society?

In the next section of his summary, Dr. Bakke deals with skilled and unskilled workers. He stresses the opinion that, for various causes which he enumerates, there is a sharp social and psychological difference between the skilled and the unskilled. "Project," he says, "a social policy into the world of skilled or even semi-skilled workers, and it will have one effect; into the world of the unskilled, and it will have quite another effect." Yet he found the sense of self-support so strong in all groups of both classes that, despite one or two examples, he is unable to say definitely that the unskilled class is more ready to rely on unemployment insurance than the skilled. That is so contrary to the general belief that note should be taken of it. It is not impossible that the current belief is based on the *a priori* reasoning that the better the social position, the greater the dislike to dependence on external help. Again, it is not unlikely that the middle class has judged the working class as it would judge itself, and has reached the conclusion that the nearer a workman approaches to the middle class, the more diffident will he be about the acceptance of outside help. If, however, the question is approached from the attitude of the insured person who claims that the money is his by right—that he has insured himself—then it is clear that whether one holding that view is skilled or unskilled will make no difference—in neither case will he feel any disgrace in accepting what he regards as his own.

Passing over a short section on Activities When Unemployed, we turn to one on Pauperisation, a subject not far removed from that we have just discussed. "Does or does not unemployment insurance produce paupers?" our author asks. "Does it decrease or increase the desire for self-support? I have briefly drawn together above the evidence from the specific items of study, such as the effect on the search for work, the effect on subsidiary employment, the effect on independent effort and the effect on moving between communities and industries. Furthermore, I have tried to picture the condition of life under which the workers of Greenwich make their living, build their homes, spend their leisure, satisfy their religious impulses, and take part in community activities. I have attempted to present an objective account of the satisfactions and attitudes which grow up in the midst of these conditions. *This general conclusion stands out: Unemployment insurance has not made paupers. It may have revealed some of them and supported them.*" The italics are the author's. Here, once more, the opinion of Dr. Bakke, as an intimate observer, must be respected, even when it opposes a view supported by not a few examples. The risk always exists that examples when they support an hypothesis which seems to stand to reason may be misleading. They are always dangerous, and a general impression may in favourable circumstances be more truly representative. It is that which Dr. Bakke appears to give us.

Indeed, the whole value of this remarkable work turns upon the author's strict impartiality. Whilst one should, as we have said, always suspect examples, generalities are equally dangerous, unless we can be quite sure of the *bona fides* of the person who makes them. Can we be sure of them in this case? Did Dr. Bakke enter upon his research with no preconceptions, with no desire to prove one case rather than another? Did he maintain throughout the detachment of an assessor, or was he moved by his intimacy with the unemployed to a sympathy with them which may have distorted his judgment? We cannot say. We do not know how long he spent in Greenwich, and how genuine his intimacy with the workers and loafers was. What we do know is that he presents his case with a shrewdness of observation which is itself convincing, and that he offers arguments which find their mark. It is concerning his deductions from his observations and arguments that there may be differences of opinion. They will not alter the fact that here is a book which none who are interested in one of the great social problems of the day should fail to read.

Neon Tube Practice. By Dr. W. L. Schallreuter. London: Blandford Press, Ltd. Price 10s. 6d.

Neon tube lighting for advertising has made such rapid progress within recent years that the manufacture and handling of luminous discharge tubes must now be a subject in which many people are interested. As far as we are aware, however, this is the first book of its kind published in this country. Electrical engineers and particularly those specialising in lighting should find the volume of considerable interest and assistance, for although the theoretical side of the subject has not been neglected, the author has adhered mainly to practical considerations. The physical and electrical conditions of a gas are explained in a more or less popular way, and considerations relating to the structure of the atom and other purely scientific theories are avoided. Readers who have hitherto given little or no attention to the subject will find nothing in the volume to trouble them. The author's long association with the manufacture and application of neon tubes has enabled him to throw much light on the difficulties that have been experienced in their development and on problems that still await solution, such as that of providing a wider range of colours.

In an appendix to the volume there is an interesting review of patent literature in which it is shown that a great number of improvements on the earlier tubes are protected. It also is shown that the present manufacturing methods, although giving satisfactory results, have by no means reached perfection, and are not so complete as other similar processes employed, for instance, in the valve and lamp industries. The next step in this direction, it is explained, will be to render the pumping of the tubes independent of personal attention, a problem which at the moment is not completely solved. The high-tension installation is said to continue to give rise to a great number of difficulties and its reliability still leaves something to be desired.

The study of the artistic side of this new means of advertising is considered to be in its infancy. Neon signs of to-day, Dr. Schallreuter contends, bear no relation to the architectural features of the building, and architects are far from being fully acquainted with the essential requirements and special possibilities of tubular lighting Representative chapter headings are the Gas as a Conductor, the Rare Gases, Electrodes, the Positive Column, the Electrical Supply, Air Pumps and Vacuum Technique, Glass Bending, Pumping and Filling, Ageing and Testing, the Practical Use of the Neon, the Erection of a Neon Sign, Hot Cathodes, and Low-tension Neon Tubes.

SIXTY YEARS AGO.

At least one British railway protects itself against claims for damages arising from unpunctuality of its trains by announcing in its general regulations that the published times of departure are not those at which the trains will start, but those before which they will not start. It is doubtful whether an action under this head would to-day have a greater chance of succeeding than, say, one in which damages were claimed against a medical practitioner for professional incompetence. It was not, however, always so. In our issue of December 12th, 1873, for example, we commended to the attention of British railway travellers the successful action for damages for delay in the performance of a journey brought by a passenger against the Belgian State Railways. The train had been delayed for three-quarters of an hour near Charleroi as a consequence of the line being blocked by goods wagons. The traveller sought 300f as damages for the delay to which he had been exposed. The railways resisted the demand, contending that the delay was the result of inevitable accident, and that in any event no compensation greater than the amount of fare paid could be claimed. The Court overruled the railways on the second-named point. As regarded the first, it found that the blocking of the line by an accumulation of trains constituted a fault on the part of the administration, and that the administration was bound to assure a free passage and the punctual arrival of the trains under its control. It awarded the plaintiff 150f. as damages. In another paragraph in the same issue we read that a Railway Travellers' Protection Society had been established recently in this country with the prime object of securing safety, punctuality, and comfort in railway travelling, and to receive and investigate complaints against railway companies under these and other heads. In yet another paragraph we find a side light on one cause of unpunctuality then prevailing on British railways. A memorial signed by 650 enginemen had, we read, been addressed to the Board of the North-Eastern Railway in which a plea was made for the better working of the block signals. The men complained that the auxiliary or distant signal was not operated when a train was required to stop, and that at many stations and block cabins they could not see the home signal until they were within a short distance of it. They also complained that the auxiliary wires were kept so slack that they would not raise the signals in a manner which permitted them to be understood. The enginemen suggested that if these defects could not be altered, the running time of the trains should be increased sufficiently to enable them to stop at all cabins to ascertain if the line were clear.

The "Jiges" Steam Boiler.

By Dipl.-Ingenieur E. PRAETORIUS, Berlin-Zehlendorf.

General Description.

THE Jiges boiler here described was invented and designed in 1925 by a well-known Swedish boiler engineer, Mr. J. G. Sandwall, and is patented in sixteen different countries. The name " Jiges " is only a registered designation, formed by Mr. Sandwall's initials, J. G. S. It is a water-tube steam boiler of the sectional type, with a number of water-filled straight tubes inclined at 15 deg. to 20 deg. to the horizontal forming the principal heating surface, and so far it resembles many other water-tube boilers.

The way in which the front and rear ends of such tubes in water-tube boilers in general are mutually united for co-operation, and connected with the steam drums, differs widely in different types and determines the properties of the boilers in regard to capacity, safety and economy. In boilers of the Babcock and Wilcox type, the water tubes in the tube bundle are arranged in vertical groups or sections, each such section consisting of a number of tubes connected at each end to vertical headers, which at their upper ends are united with the common steam drum or drums.

In the Jiges boiler the tube bundle is subdivided into horizontal groups or sections, all tubes belonging to one and the same section being placed beside each other and connected at each end to horizontally placed headers—one in front and one, situated on a lower level, in the rear. These headers are made of straight solid drawn square tubes, subsequently bent at the middle into a blunt V, so that each half of each header forms an angle to the horizontal of 15 deg. to 20 deg., or the same inclination as that of the water tubes themselves, in order to make the water circulation through the whole system as even and lively as possible.

From each end of these headers run tubes connecting the headers with the steam drum above. Through the tubes at the front end (the " risers ") the steam produced enters into the steam drum, while through the rear tubes (the " downcomers ") the water is fed from the drum to the section.

The diagram, Fig. 1, shows in full lines one such complete section consisting of water tubes, front and back headers, risers, downcomers, and their connection to the drum. Dotted lines indicate how a number of such sections may be piled up on each other, and how they are coupled to the steam drum. Each such section forms a small closed boiler in itself, with independent steam delivery to, and independent water supply from, the drum above, and boilers of any desirable size can be built up by combining a suitable number of such sections of proper size into a complete unit.

The connecting tubes—risers and downcomers—form a part of the total heating surface, and it is evident that in the way they are formed they admit the headers of each section to move freely without straining any joints, thus making the whole boiler system elastic. It is also evident that as all the straight water tubes belonging to one section lie practically in the same heat zone, they all expand and contract alike, and that as the headers can move freely all additional strain in the tube joints is completely avoided and perfect tightness, even by sudden changes in temperature, is insured.

Furthermore, since all the tubes of one and the same section are alike and exposed to practically the same temperature, the steam-producing conditions must be the same in them all; that is to say, the steam production, quality of steam, and speed of flow, &c., must be practically the same in all these tubes. The steam-water emulsion from each section being of the same quality, is discharged directly into the steam drum above without mixing or interfering with that from other sections, thus differing radically from the conditions in boilers with vertical sections. Fig. 2 shows a Jiges boiler with 450 square metres=about 4800 square feet heating surface.

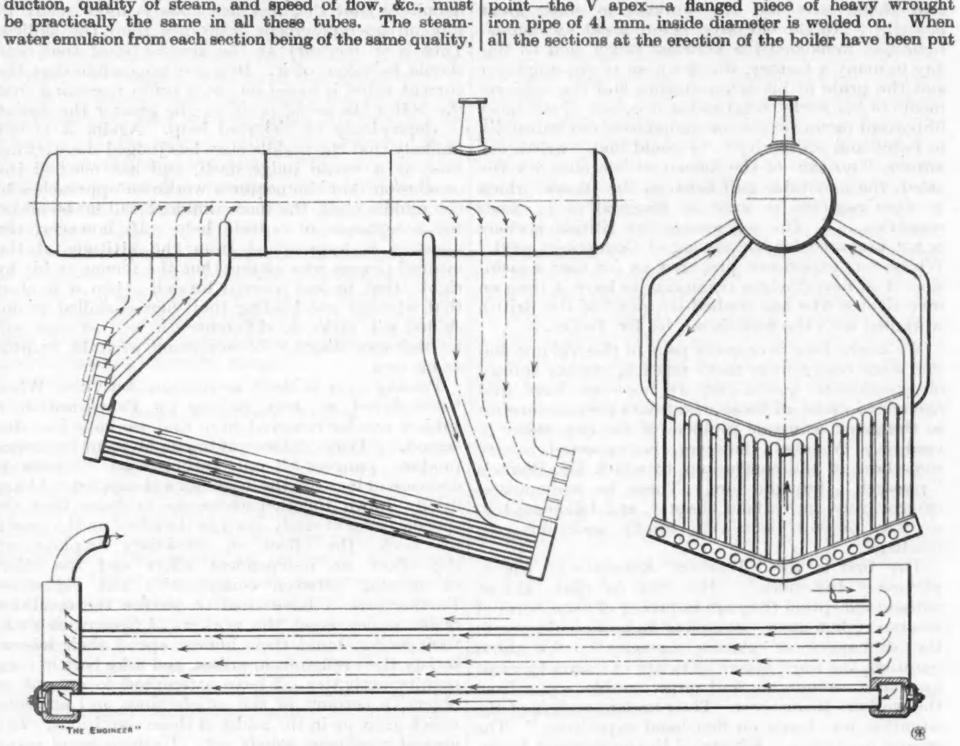

Fig. 1—Diagram of Tube Arrangement of Jiges Boiler

Manufacture.

The manufacture of a Jiges boiler is very simple, and only those machines and tools that are commonly used in any boiler shop are needed. The square tubes for the headers are received from the rolling mills in desired lengths. The internal size is generally 140 mm. by 140 mm. and the thickness of walls has been 19–22 mm. for boilers already built. The end plates at each end of the headers are electrically welded in. The ends of the square tubes are warmed, the roughly fitting square bottom pieces—generally 26–28 mm. thick—are pushed in, and the ends of the headers slightly pressed inwards, and finally the welding is carefully done. The tube holes in the end plates are bored, the header filled with sand, and the bending into V shape is done in an hydraulic press, after the header has been heated in the middle portion, where the bend is to occur. The tube holes and their opposite cleaning holes are afterwards bored out.

On the back of each rear header and at its lowermost point—the V apex—a flanged piece of heavy wrought iron pipe of 41 mm. inside diameter is welded on. When all the sections at the erection of the boiler have been put into place, all these pipes are connected to and by a common drain pipe at the bottom of which the drain valve is placed.

The rear headers are fixed rigidly in place, while the front headers are left free to move.

All the sections—front header, straight water tubes, and back header—are made completely ready in the shop, and there tested under water pressure, and transported to the erecting place ready to be put into position. The risers and downcomers are mechanically bent to exact shapes, and experience has proved that they afterwards fit exactly in their places, so that no unnecessary fitting has to be done, but simply the expanding of the tube joints.

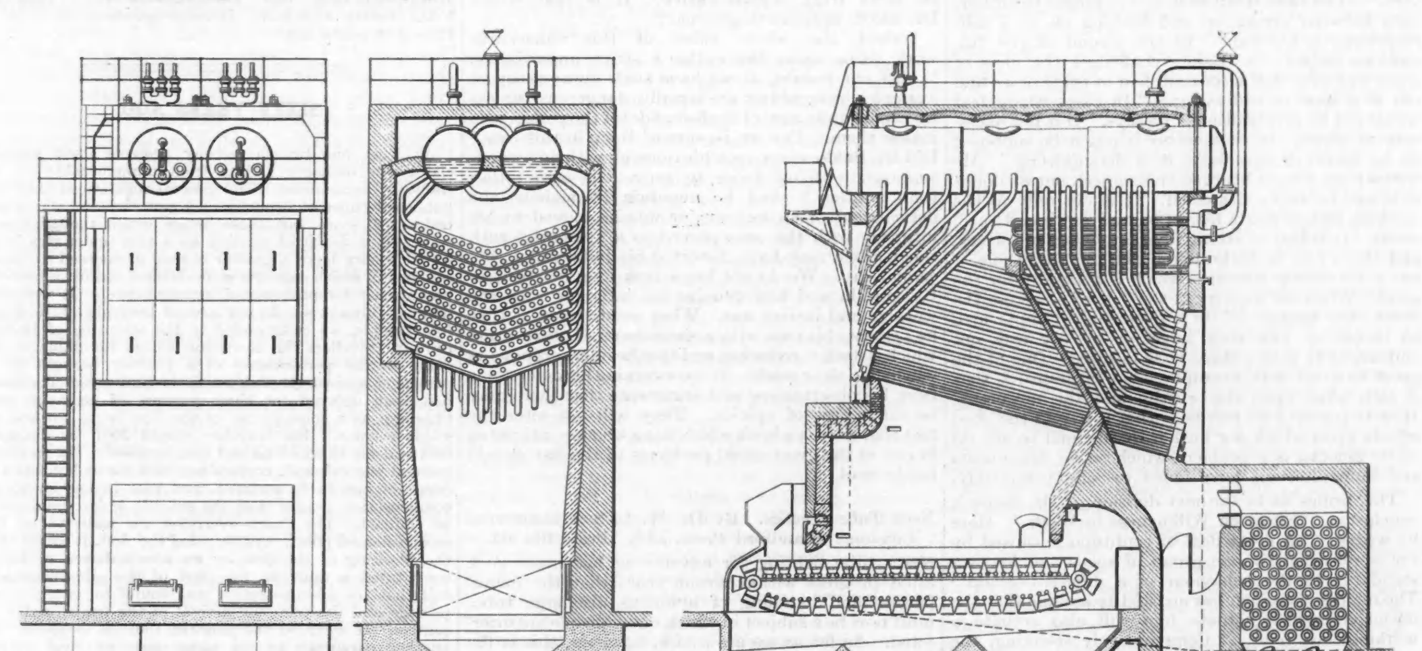

Fig. 2—Jiges Steam Boiler

The framing of the boiler is, of course, ready built in the shop, and after arriving at the site is mounted and screwed together. Riveting, drilling, or similar work at site is completely avoided.

In Sweden the following industries are using Jiges boilers—see Table I.

TABLE I.

Firm.	Number of boilers.	Working pressure. Atm=lb.	Heating surface. Per boiler. m²	Heating surface. Per boiler. square feet.	Heating surface. Total square feet.
1. The Kungsfors Spinning Mill, Skene (Boras)	1	25=375	165=	c/a 1800	1,800
2. The Strömsnäs Paper Mill	1	25=375	350=	3800	3,800
3. The Jönköping Match Factory	1	15=225	300=	3200	3,200
4. The Swedish Sugar Works Co.	2	25=375	450=	5000	10,000
5. The Swedish Sugar Works Co.	3	30=450	450=	5000	15,000
6. The Cement Factory, Limhamn	2	25=375	350=	3200	6,400
Total	10	—		—	40,200

To these are to be added the following Jiges boilers outside Sweden :—

Denmark.—Two boilers for 375 lb. pressure and total heating surface 5000.

Belgium.—Thirteen boilers for 300–450 lb. pressure and total heating surface 36,000.

The total list comprises twenty-five Jiges boilers for working pressures of 225–450 lb. and with a total heating surface of about 81,000 square feet. The smallest of these boilers are only 70 square metres—say, 750 square feet—heating surface and the largest of 600 square metres, or about 6500 square feet heating surface, and for a working pressure of 30 atm.—say, 450 lb. per square inch. The last boiler is fitted with a powdered coal furnace.

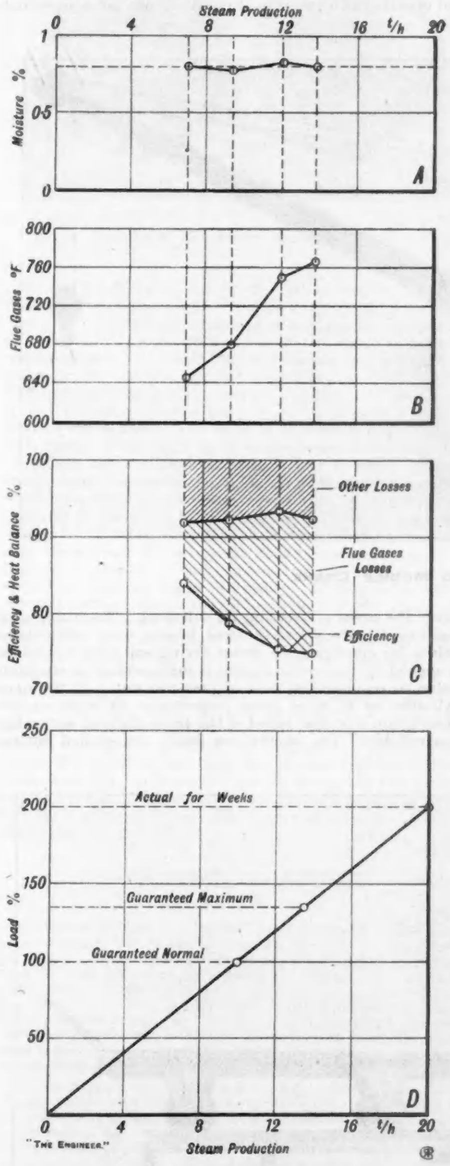

FIG. 3—TESTS OF BOILERS

KUNGSFORS SPINNING MILL.

A few notes about the Swedish plants may be useful. The Kungsfors Spinning Mill, Skene, belongs to the firm Boras Väveri A/B, Boras, Sweden. In it spinning and dyeing are done, the latter process being the principal steam consumer and a very unpleasant one, as the consumption is very varying. The firm ordered in 1926 a Jiges boiler —the first one built—of 165 square metres (about 1800 square feet) heating surface and for a working pressure of 25 atm. (=375 lb. per square inch). The intention was that the steam should, after having passed a steam turbine and a steam accumulator, go to the dyeing department, but as from the beginning neither the steam turbine nor the accumulator was at hand, the boiler during the first period was called upon to deliver steam of only 7–9 atm. (105–135 lb.) pressure directly for dyeing purposes. As that meant that the boiler should, like an accumulator, be able to respond quickly to very sudden changes in steam consumption and to deliver at intervals considerably more steam than the normal and maximum steam production, it was provided with three large steam drums in order to give a large water volume and a large free water surface.

The boiler is fitted with a steam superheater, but no economiser. The stoker is of the "Dano" underfeed type. Cold—that is, not preheated—air is used, but provision is made for the installation of an air preheater later. The fuel is English Duff coal of 5500–6000 fr.-cal. (=9900–10,800 B.Th.U.). The boiler was guaranteed to deliver 4·5 tons of steam per hour when using cold air for the combustion, and 7·5 tons per hour when using preheated air. It has been in regular service since November, 1927.

In Table II. the second column shows the result of test made under the supervision of the Federation of the Boiler-owners of S. Sweden. Notwithstanding the fact that the economiser was not in use and that cold combustion air was used, the boiler produced nearly twice as much steam per hour as was guaranteed, or 8·62 tons per hour, corresponding to 52·2 kilos. per square metre of heating surface. This production was easily reached and that, too, without priming, and although the feed water was anything but good, the content of sodium carbonate being quite high. According to the report of the test, considerably more steam could have been produced if the stoker had been able to burn more coal or if a better quality of coal had been used; but the chimney draught was insufficient for increased forcing.

The thermal efficiency proved to be 75 per cent. for the boiler and superheater, which is regarded as good under the conditions, the temperature in the escaping gases being not less than 424 deg. Cent. (nearly 800 deg. Fah.) on account of the absence of economiser and air preheater surfaces. By introducing an air preheater the thermal efficiency would undoubtedly rise to at least 85 per cent.

Fear that the bent side tubes (risers) would, on account of the bad feed water, give trouble with scale deposits, have fortunately not been realised. Scale is removed from the straight tubes in the usual way.

STROMSNAS PAPER MILL.

The Strömsnäs Paper Mill, Strömsnäs Bruk, Sweden, ordered about at the same time as the above-mentioned firm a Jiges boiler of 350 square metres (=3800 square feet) heating surface and for 25 atm. (=375 lb.) working pressure, and this boiler has also been in use for about 5½ years under a pressure of 150 lb., and after that of 375 lb. It is provided with a superheater and air preheater, but no economiser.

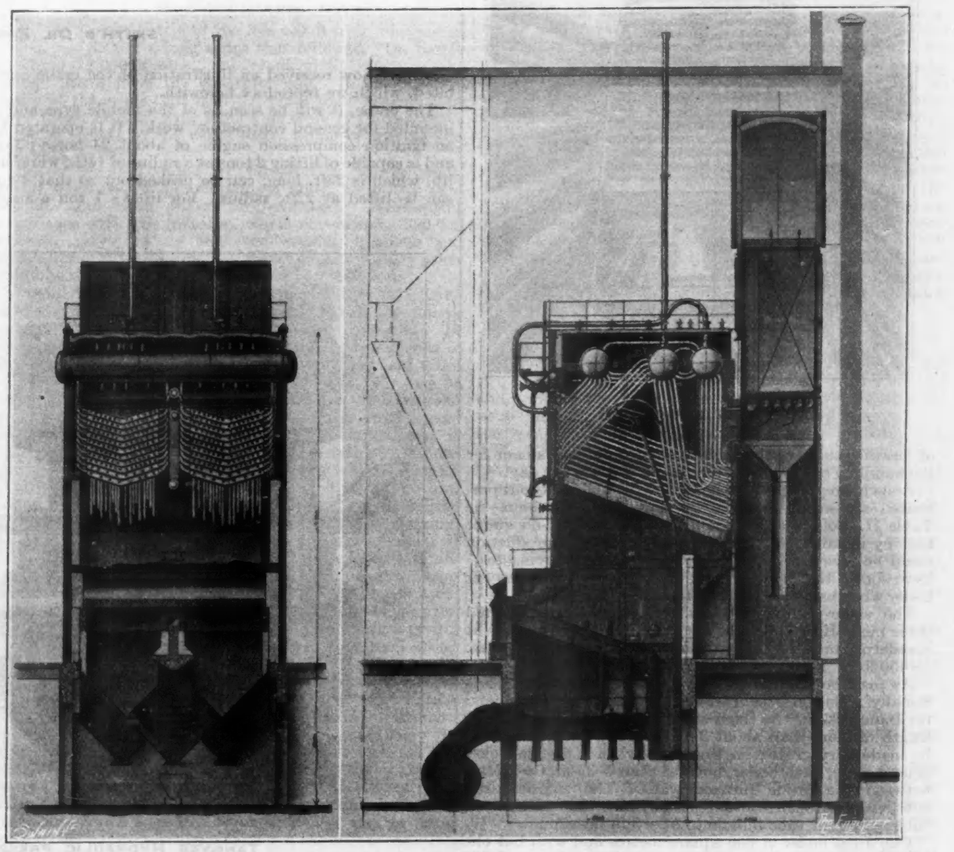

FIG. 4—BOILER FOR A SUGAR WORKS

The stoker is a "Pluto," which is suitable for fuels of the very varying kinds and especially for the Swedish coals of low quality used in this case. These coals contain about 15 per cent. ashes, 16 per cent. moisture, and the heat value is 5000 fr.-cal. per kilogramme (=9000 B.Th.U.) Twelve such stokers have been working since 1917 at the Ormastorp power station with a fuel containing not less than 50 to 60 per cent. of ashes and a heat value of only about 5000 B.Th.U.

TABLE II.—*Evaporation Tests with Jiges Boilers in Sweden.*

Plant	Kungsfors spinning mill	Skivarps beet sugar factory

Other losses, per cent.	4·2	7·2	5·1
Total losses, per cent.	25	18·5	25·3

* Two boilers.

The guaranteed maximum steam production per hour with these coals was 10 tons, but the general average load is 12 to 13 tons per hour, and the boiler runs for weeks, yielding an average of 16 tons per hour and can be forced to deliver 20 tons of steam per hour, which corresponds to about 55·2 kilos. per square metre, or the same as in the case of the Skene boiler before described. Fig. 3, Diagram D, gives further details.

Official tests made in 1928 showed the efficiency of the boiler and superheater to be 84 per cent.—see Fig. 3, Diagram C. On different occasions during the year several other tests were made, partly with and partly without preheating of the combustion air and at different loads, and the results will be found illustrated in Fig. 3. As will be seen, the moisture of the steam before the superheater and at all loads is constant and exceptionally low—0·8 per cent.—an evidence of the excellence of the circulation. As during the past years experience has shown that, even with very sudden changes in load and the greatest steam production changes in moisture of steam before the superheater, and noticeable variations in the temperature of the superheated steam, never occur, one may be entitled to consider that the line of moisture in the steam, within the limits of the loads in question, runs horizontally, as seen in the diagram.

MATCH FACTORY AT JONKOPING.

Since the middle of 1928 a Jiges boiler of 300 square metres (=3200 square feet) has been in daily service at the match factory in Jönköping, Sweden. The working pressure is 15 atm. (=225 lb. per square inch). The boiler is provided with a superheater, but there is neither economiser nor air preheater. The furnace is of the factory's own design, and built as a gas furnace for the use of almost all sorts of wooden rubbish from the factory. A mixture of fifteen different kinds as generally used has about 40 per cent. moisture and a calorific value of 2400 fr. heat units (about 4300 B.Th.U.) per lb. Even by using such a poor fuel, and under the very unfavourable conditions prevailing, the efficiency of the boiler and superheater has proved to be 70 per cent. at an output of 31 kilos. steam per hour per square metre, or 9·3 tons per hour.

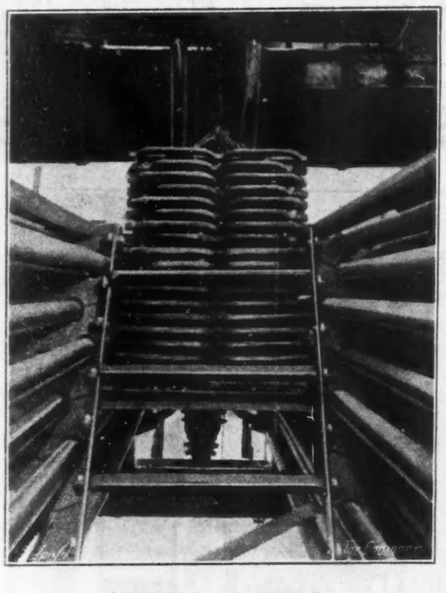
This is, of course, not the limit by far, but as the draught in the chimney at present is, there is no possibility to force the furnace more.

This boiler is working under quite normal conditions, and never exposed to sudden changes or any extraordinary load.

SWEDISH SUGAR WORKS COMPANY.

During the sugar campaigns of 1930, 1931, and 1932, this very extensive concern had two Jiges boilers, each of 450 square metres (about 5000 square feet) heating surface, and designed for a working pressure of 25 atm. (375 lb.) in use at the beet sugar factory in Skivarp.

As a projected steam turbine has not yet been installed, the working pressure is only 7–8 atm. (105–120 lb.). With two boilers, with together only 900 square metres of heating surface, the factory easily produces steam for the handling of some 1500 tons of sugar beets per day.



[FIG. 5—SUPERHEATER]

Tests have proved that the boilers together, without preheated air, easily produce 30 tons steam per hour—as Table II., Cols. 3 and 4 confirms—and there is no doubt that by installing an air preheater the normal production could be raised to 40 tons per hour. Short forcing tests have shown that a steam production of up to 26 tons per boiler when using cold air is attainable.

The same company, early this year (1933) ordered three more Jiges boilers of the same size for its factory at Hasslarp, but for a working pressure of 30 atm. (=450 lb.). These boilers are now in course of erection.

As may be seen from Fig. 4, these boilers are exceptionally wide, on account of the buyer's special demand for Danostokers. As these stokers do not allow a furnace length of more than about 3 m. (=10ft.), the width must be made very great; in this case, when a double-stoker is used under each boiler, not less than 5·35 m. (=17½ft.), between the inside furnace walls. The characteristic subdivision into horizontal sections limits the width of one tube system or tube bundle to a certain maximum.

One Jiges boiler of 600 square metres and with but one tube system is in course of construction and one of 800 square metres has been designed. For boilers over 800 square metres two tube systems will be necessary.

In the 450 square metre boilers here described, two tube systems are used on account of the exceptionally great width of the furnace, and the superheater is placed between the tube bundles (Fig. 5). This arrangement has proved satisfactory, and the superheater works out remarkably small—only 22 square metres—and still very effective, exposed as it is to the radiating heat. It is made of specially fireproofed steel tubes, and experience has shown that the steam temperature is very constant.

CEMENT FACTORY, LIMHAMN.

This factory generally buys electric energy from an outside power company, but has its own steam power station as reserve. During the year 1931 two Jiges boilers, each with 350 square metres heating surface, and for 16–25 atm. working pressure, were installed. They are provided with superheaters and common economisers.

The delivery tests showed that the contracted capacity was easily reached and surpassed, and the efficiency of the boiler, superheater and economiser was at maximum load, 80 per cent.

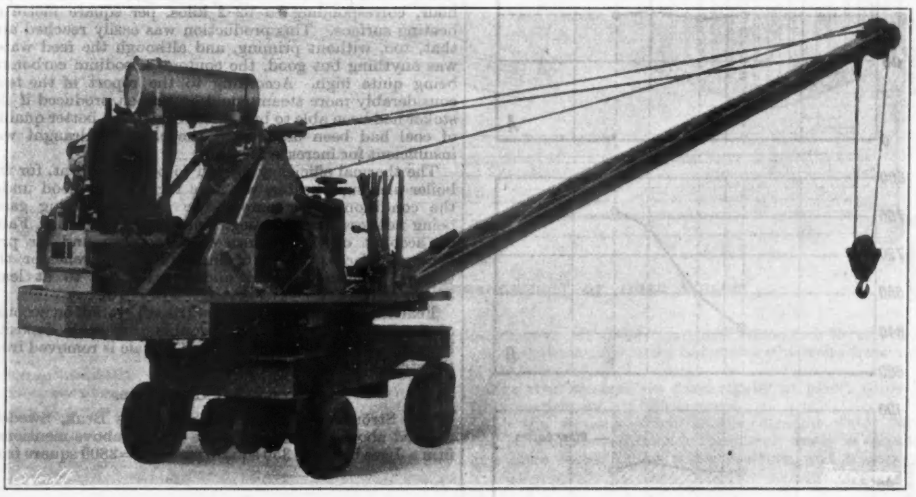
SUPERHEATERS.

In Swedish-built Jiges boilers, with but one tube system, the superheaters are always placed after and above the tube bundle, but may be, as in most of the boilers made by the Belgian licensees, A. F. Smulders, placed after the lowermost section thereof. The superheater may be placed in any desirable place, as this is without any influence on the water circulation in these boilers. In most cases the superheater can be taken out at the back, thus making it possible to build boilers side by side without open spaces between the wide walls.

A Contractor's Crane.

In connection with the Public Works Exhibition at the Royal Agricultural Hall, we made brief reference to the exhibit of Thomas Smith and Sons, of Rodley, near Leeds, and have now received an illustration of the crane exhibited, which we reproduce herewith.

The crane, it will be seen, is of the mobile type and is intended for general contractors' work. It is operated by an ignition compression engine of about 24 horse-power and is capable of lifting 2 tons at a radius of 14ft., while the jib, which is 25ft. long, can be peaked out so that ½ ton can be lifted at 22ft. radius. For lifting 1 ton a single purchase is used, and then the lifting speed is 160ft. per minute. For greater loads a double purchase is used and the speed is reduced to one-half. The crane can be slewed at the rate of five revolutions per minute and the travelling speed is either 4 or 1½ miles per hour. The crane has a fuel consumption of ¾ gallon per hour.

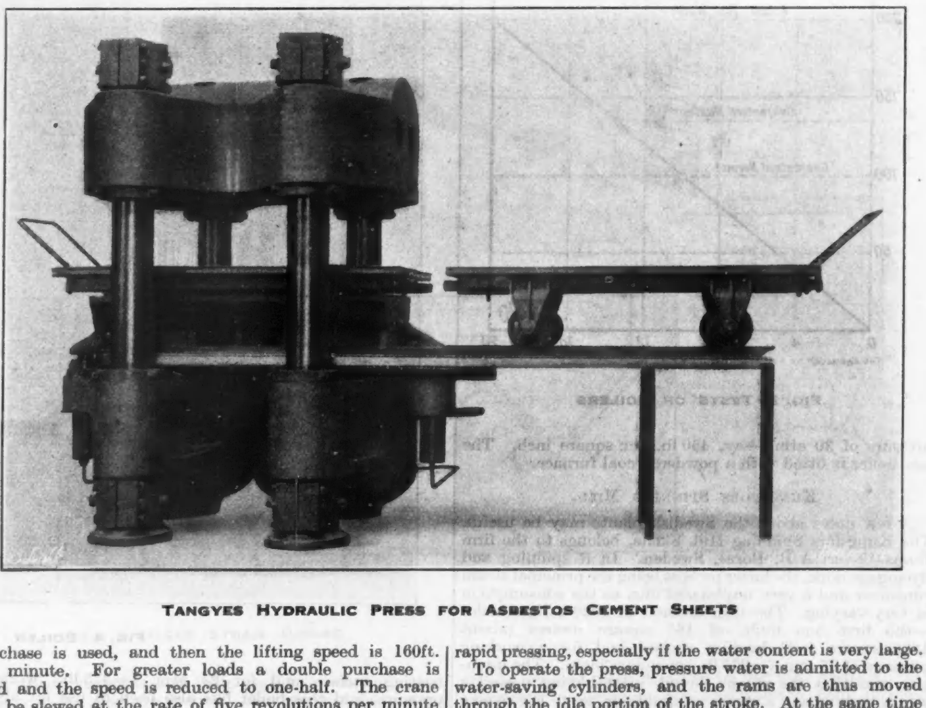


SMITH'S OIL ENGINED MOBILE CRANE

A Hydraulic Press.

The hydraulic press illustrated was made by Tangyes, Ltd., of Cornwall Works, Birmingham, and was designed for the pressing of asbestos cement sheets measuring up to a maximum of 8ft. by 4ft. It is capable of exerting a pressure of 4628 tons. The complete press weighs approximately 80 tons, and is one of the most powerful machines every built for this type of work. It is fitted with two main rams, each 32in. diameter, working in cast steel cylinders. A water-saving device is incorporated in the action of the press, and for this purpose two 5in. diameter rams working in forged steel cylinders are fitted in the main cylinder casting, the rams being connected to the moving table. The head and table of the press are steel castings of massive construction. The columns are made of special quality high-tensile steel, heat treated and normalised, and screwed with a buttress thread to withstand the load. The column nuts are steel castings made in halves, screwed and secured round the columns by the bolts shown. The unit is provided with two trolleys, as shown in the illustration, on to which the material that is to be pressed is loaded. Whilst one trolley is being loaded, the material on the other is being pressed. These trolleys are built up of steel sections, and are provided with troughs round the working surface for collecting and running off the water forced out of the sheets during pressing. The runners are arranged for running on rails and are fitted with ball bearings for easy working. As will readily be seen from the illustration, the trolley is run over the press platen, and then lifted clear of the rails during the pressing stroke in such a manner that the total load is only received on the surface plate in compression. A three-throw vertical motor-driven Tangye pump is supplied to feed the press, and operates at a pressure of nearly 3 tons per square inch when the press is exerting its full load. The valve gear consists of two stainless steel blocks with screw-down valves for operating the water saving and main cylinders. A special by-pass arrangement is incorporated in the main valve to regulate the flow of pressure water to the main cylinder, as it is of great importance in work of this description that the speed of the press shall be accurately controllable. The sheets can easily be spoiled by too rapid pressing, especially if the water content is very large.

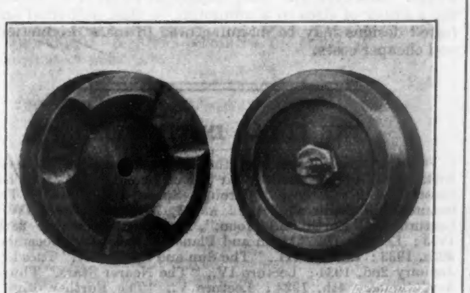
To operate the press, pressure water is admitted to the water-saving cylinders, and the rams are thus moved through the idle portion of the stroke. At the same time gravity feed water is drawn into the main cylinders from an overhead tank through a non-return valve. When the resistance becomes too great for the small cylinders,



TANGYES HYDRAULIC PRESS FOR ASBESTOS CEMENT SHEETS pressure water is admitted to the main cylinders, and thus is only used for the actual pressing operation. After pressing the water is exhausted back to the feed tank. The non-return valve prevents the high-pressure water from flowing into the low-pressure mains when the pressure is on. Although water has been mentioned previously, this actual plant is to be operated with oil.

An Oiliness Comparator.

THE "oiliness" of a lubricant is a measure of its capacity to form a permanent lubricating film on metal surfaces. Physically, it is now recognised to be intimately connected with the union of the oil and metal molecules. It is the essential property which imparts to any oil its lubricating properties. Several machines, generally of a complicated and costly character, have been devised to measure quantitatively the oiliness of a lubricant. In practice a rough-and-ready test of an oil consists of rubbing it between the finger and thumb, but in actual fact such a test can only give a rough idea of the viscosity of the fluid, a property which many other substances destitute of oiliness possess in common with lubricants. The "Aptol" oiliness comparator illustrated herewith has been produced by Sir W. H. Bailey and Co., Ltd., of Salford, Manchester, with the object of providing a simple, cheap and easily applied means of comparing the oiliness of two oils. The device consists of two small cylindrical pieces of cast iron which register together by means of a short pin in one of them and a central hole in the other. The portion with the pin has an annular face about $\frac{1}{8}$in. wide. The other portion has a ridge cut into three sections formed on its face. The crest of this ridge is of a small, but finite width, and as a consequence when the two parts are applied together with a fair amount of force, the pressure between the ridge and the annular surface assumes a considerable value comparable, in fact, with the pressure existing in a loaded bearing. To carry out a test with the device the surface of the ridged portion is smeared with the oil and the two parts, held one in each hand, are brought together. While under fair pressure they are slowly twisted one upon the other. If they turn with a smooth sliding motion, the oil has a high degree of oiliness. If, however, the oil is deficient or poor in this quality, the two pieces tend to chatter or grip, and a distinct feeling of the surfaces biting on one another is experienced. It is essential that after each test the highly tenacious oil film adhering to the surfaces should be removed, in order that it may not upset the results obtained with another oil. For this cleaning process two rubbings with cloths soaked in benzol or petrol are recommended. After several dozen of tests have been made the annular surface becomes worn and has to be repolished by removing the central pin and rubbing the surface on a piece of polishing paper laid on a piece of glass. The ridges of the other portion rarely require polishing.



BAILEY'S OILINESS COMPARATOR

WEATHERING TESTS OF PAINTS.—In connection with a paragraph on page 431 of our issue of November 3rd, the Pyrene Company, Ltd., owners of the patents for Parkerising, remark that Mr. O. Lindermayer's complete article does not deal unfavourably with the Parker process, but only with the particular tests which were started under unfavourable conditions some time ago, and which, it is understood, are still continuing. We may add that the deduction from the words used in our paragraph would support the view that the investigation is proceeding.

A FORCE-FEED OILER.—Joseph Kaye and Sons, Ltd., of Lock Works, Leeds, and 93, High Holborn, W.C.1, have sent to us for inspection a sample of their latest pattern seamless steel forced feed oil can. The body, which is heavily tinned, is serrated where it makes a junction with the cover, in the manner familiar in Kaye cans for many years. Apparently some trifling trouble had been encountered with the thumb button on the plunger, as we are specially informed that in this pattern it has been improved, now being made of sheet brass which is screwed on to the plunger wire before soldering. The spout which is double-wrapped, is fitted with a small perforated strainer. This make of oil can is so well known to engineers that we need not call attention to its robustness; the cans are certainly built for rough usage.

THE ECLIPSE 48. TOOL.—The "Eclipse" 48. tool made by James Neill and Co. (Sheffield), Ltd., consists of a double-ended metal handle slotted and tapped for a set-screw at either extremity. The end of the blade is ground off at an angle and is firmly held in either slot when the set screw is registered with the hole in the blade portion and screwed home. It is supplied complete with short lengths of hack saw blades specially prepared and shaped for its own use. In addition, other varieties of blade have been devised for it. These blades take the forms of a screwdriver, a slitting knife, a file, scrapers, and double-edged saws for cutting slots of different thicknesses. The angle at which the blade is held relatively to the handle is different according as the blade is fixed at one end or the other of the handle. This variation of setting greatly increases the range of usefulness of the tool in tackling many awkward jobs.

Diesel Electric Units of the Buenos Aires Great Southern Railway.*

By P. C. SACCAGGIO.†

BEFORE proceeding, I should like to make it clear that the name "Diesel," which I have used, in no way implies that our motors embody the system devised by Dr. Diesel many years ago. Several British names have a far more legitimate right to be attached to our "compression ignition engines." However, the name "Diesel" has the advantage of being short, and it generally implies "compression ignition engines."

For many years the suburban traffic of the Buenos Aires Great Southern Railway increased at such a rate that, sooner or later, steam traction could no longer fulfil requirements, and the only alternative, as far as could then be seen, would have been electrification. The lay-out of the Southern suburban system consists of three radial lines centring at Plaza Constitución terminal, involving approximately 350 kiloms. of single track, with many junctions and crossings. It is problematical whether suburban services are, as a rule, permanent paying propositions or not; therefore any increase in the already large capital invested in providing for such services is always subject to serious consideration, and naturally the railway authorities felt that before embarking on electrification, other possible systems of traction should be studied.

In the early 'twenties, Diesel traction received an impetus by a few large-sized locomotives built for the Russian railways. Other countries also showed interest in this system of traction, and various attempts were being made. On inquiry we found many manufacturers willing to supply anything that was wanted, but a glance at the majority of the proposed engines did not prove convincing; it was therefore decided to make various visits in order to see some of the engines built for railway work. In the end, although no suitable engines so far built fulfilled our requirements, we obtained sufficiently convincing proofs that engines of about half the size required for the heavy trains we had in mind could be satisfactorily built; accordingly, studies of Diesel-electric power-houses were proceeded with, which finally resulted in a scheme of two eight-cylinder, 700-revolutions, 600 H.P. motor electric units for a five-coach train. This proving satisfactory to the railway authorities and the consulting engineers, Messrs. Livesey, Son and Henderson, two such units were ordered with the object of running them independently or coupled as one train unit.

It was never expected that, from then on, all would be "plain sailing." The inevitable troubles that invariably occur with such enterprises were fully expected. Unfortunately (or I should say fortunately), when the sets arrived, we got all we expected and a good deal more. Now that these units are most well behaved, doing excellent work with the least care bestowed upon them, and with every chance of reaching a good old age of about 1,500,000 kiloms., it is pleasant to look back on past troubles and feel that they were a blessing in disguise. I am convinced that, but for the fact that they did occur, the design and construction of the engines subsequently built and recently received would not have yet been possible. In troublous times real knowledge is acquired, and I shall now tell you a few of the main headaches and how they were cured.

ENGINE FAILURES.

On the first trial trip of the five-coach train one piston failed, the first of a long series that followed. On barely reaching 12,000 kiloms., one crank shaft broke at the second crank from the generator end. In the interval many of the studs that held the main shaft bearing caps were found broken, with a good mixture of broken valve spindles, cracks in the white metal lining of the big end bearings, &c. &c.

Piston troubles ended by substituting the originals, which were cast of an aluminium alloy, by others of a special aluminium alloy drop-stamped. Subsequent experience with this material, which covers some 200,000 kiloms., convinced me that the wearing qualities and durability of these new pistons are far superior to any other piston material I know of, including best cast iron.

The failure of the shaft was caused by the engine momentarily running at the critical speed of the fourth order every time the load was suddenly removed. In engines with eight cylinders in line, the critical speeds of shafts that fall within or near the working range are those of the fourth and eighth orders. The best that can be done is to keep the working revolutions of the shaft well away from them. The critical of the eighth order occurs below the working rotary speed of the engine, and is usually passed at starting at a very high rate of acceleration, so that the time interval in passing it is sufficiently small to avoid harmful synchronisation with the natural period of vibration of the shaft. On stopping the engine the effects of this critical are felt more than in starting, because deceleration is slower and causes the rotation of the shaft to remain for a slightly longer period in its vicinity. Good designers take care that the working revolutions of the engine are about 15 to 20 per cent. above or below these two critical speeds, and as long as the unloading of the engines is done gradually, thus giving ample time for the speed governor to act, the rotary speed of the shaft never reaches the critical speed of the fourth order. In train operation the power to the traction motors must be cut off almost instantaneously, but the friction and inertia of the parts of the fuel control mechanism operated by the speed governor of the engine delay its governing action, so much so that for a short period the engine accelerates, and does (or may) reach the critical rotary speed of the fourth order. Should such conditions occur frequently, sooner or later a broken shaft will be the result. Such fractures occur suddenly, and do bring home to the uninitiated the meaning of the effects resulting from torsional vibrations if they happen to synchronise with the natural period of shafts.

Means to prevent such serious troubles appeared a most formidable task. Dashpots and other mechanisms for delaying motion of the control handle when the train conductor wished to cut off power from the train motors were thought of, but found impracticable, and it was only after many disappointments that a simple appliance was found by means of which the fuel supply to the engine cylinders is cut off as soon as the train conductor begins to move the control handle in the direction of unloading. This new arrangement not only avoided engine racing and the breakage of shafts; it also cured a series of other troubles, such as the breaking of studs of the main shaft bearing cap already mentioned, pipes, joints of all descriptions, and other small breakages and slackness that used to occur in the vehicle body; in fact, the vibrations that were set up on the whole structure when the engines were suddenly unloaded have disappeared, and we now realise how formidable they were, although at first we were more or less inclined to accept them as inevitable evils.

I have mentioned valve failures. These usually occurred at the end of the stem where it was screwed to a tappet head or where the stem joined the valve body. A modified design that does away with the threading of the stem, combined with a more uniform change of cross section from stem to valve, ended these troubles.

The cracking and peeling away of the anti-friction metal lining from the bronze backing of big-end bearings was overcome by reducing the thickness of this metal to about $\frac{1}{16}$in., and assuring good adherence to the bronze backing. We have had bearings in good condition after 75,000 kiloms., but although we knew the technique of how this work should be correctly done, not all bearings are equally successful, a good deal depends on the human element, which we are endeavouring to substitute by more certain means. The cracking of the anti-friction metal of these bearings is also influenced by incorrect combustion, or by what has come to be known as "Diesel knock," more or less recognised as part and parcel of the system. Such "Diesel knocks" act like terrific blows on all bearings and the shaft—they should never exist with well-designed injection nozzles and combustion chambers, but each engine requires individual treatment.

Failures caused by the sheer ignorance of the mechanics were by no means few. However, they have since become proficient after a good deal of intense training. I have found that the average railway mechanic is ill-adapted for this class of work. A good staff can, however, be formed from selection amongst young apprentices, who, as a rule, are keen on anything new, and after many mistakes turn out really good at their profession.

OVERLOADING.

After most of the engine defects were put right, and we hoped for better times, there still remained an important point to attend to; means to prevent train conductors from overloading the engines. The trains were put in motion and accelerated by reducing by hand the resistance of the electrical circuit of the magnetic field of the generator in a series of notches, and as the hand control was never correctly operated, the engines were most of the time either under or overloaded. To guide the conductor, signals of various sorts which indicated when the engines were approaching or had reached full load were provided, but the results were never satisfactory. Overloading of Diesel engines can only lead to slowing down, with the consequent overheating of cylinders, pistons, valves, &c., resulting in increased maintenance costs. Further, by not maintaining a steady full load on the engine, the acceleration of the train suffered. It became evident that this system of traction could never be a complete success until some automatic means was found to load up the engine quickly and maintain full load during all working periods, which was successfully accomplished some time ago by an automatic control. With this control the train conductor has no signals or other instruments to attend to—his function is reduced to moving the controller handle in one direction for starting and the reverse for stopping the train, and a casual peep at the vacuum brake gauge. By this mechanism we were also able to do away with many other electrical fittings and complications, so much so that the forty-four small conductors laid from one end of the train to the other, which we previously needed, have been reduced to ten, and we shall not rest satisfied until they have been brought down to six. If one remembers that the failure of any of these conductors interferes with the working of a train, it will be realised how necessary it is to reduce potential failures to a minimum.

FURTHER PROGRESS.

In 1930 we had made sufficient progress with the two experimental power-houses to warrant further studies and preparation of schemes for the heavier weight of train required, and the motor units lately received are the result. These new Diesel engines are probably the best of their type so far built; the general arrangement having been published in various technical papers, I assume you are acquainted with it. My opinion is that they can be made a design and type likely to remain standard for many years.

Although the suburban scheme of Diesel-electric traction is in itself most interesting, technically and financially considered, the major railway problem consists in cheapening transport generally, and in view of the potential economies of Diesel-electric traction for other work, a main line locomotive with two motor electric units duplicate with those of the power-house was ordered.

It may be of interest to know that it has been definitely proved that with the total H.P. available from the two Diesel groups, we can, on any part of our suburban system, with trains stopping at all intermediate stations, arrive at destination in the same running time that we could obtain from ordinary electrification.

It has been remarked that a suburban service worked by Diesel-electric power-houses is bound to result in high operating costs—in the first place there is the dead weight of the power-house to be hauled about with the train, also the fact that heavy block trains entail unnecessary coach kilometrage during slack periods. Taking the last objection first, there is nothing to prevent us from making the train units half the size of the high-capacity train we now fill up at all the peak hours. It would not entail any extra capital outlay in power-houses, because their design permits of their being separated into two units, neither are there any reasons why we should not add or take off vehicles from a train, but with the short time intervals between peaks (four in the day) the saving in money likely to result from so doing would not be sufficient to pay the wages of the required shunters. Regarding the objection of hauling the extra weight of the power-house, it may not be generally known that the tare weight per seat of our large-capacity train, including the weight of the power-house, is about the same as that of the modern stock used on electrified lines, and considerably less than that of the older passenger stock of those lines. The large-capacity carriages we use—entirely a Southern Railway product—permit a low tare per seat. Of course, it may be argued that the same carriages could be used on ordinary standard electrification, but that is another story; it is not quite as easy as it looks.

---

* Address to members of the Institution of Mechanical Engineers in Buenos Aires, June 28th, 1933. Slightly abridged.

† Technical Adviser, Buenos Aires Great Southern Railway.

Operating Costs.

Now a few remarks about operating costs. We obtain 1 kilowatt-hour at the traction motor terminals at the expenditure of 250 grammes of fuel oil, representing, including lubricants, a total cost of production of 1½ cents paper, or less than 0·2d. at present rate of exchange, and it should be remembered that no labour is employed for producing the necessary power. Electric energy is only used when the train is being propelled. In coasting, or at the instant of cutting off the current from the traction motors, the engines themselves are stopped, and all wastages avoided. The train conductor's wages alone represent about one-third of the cost of producing the required power. On these conditions we could afford to be extravagant in our working as far as power cost is concerned. To complete the picture of cost of power, to the cost of fuel and lubricant must be added the maintenance cost of the power-house motor electric units, plus interest and depreciation of their capital cost. As far as interest and depreciation is concerned, I have already said that the capital expenditure required for motor electric units is not more than that involved in a central power station, nor is the depreciation of a travelling power-house, as it can be built to-day, any greater. Compare the cost of 1½ cents paper per kilowatt-hour produced by the Diesel motor units with the price usually paid for electric current delivered at a central station bus-bars. Add to this cost that represented by the losses incurred in transmission, track leakages, and the electrical energy forcibly wasted in resistances, &c., and you will find that the difference in cost of power between the two systems will leave a substantial margin in favour of Diesel traction, and more than sufficient to cover maintenance, interest, depreciation, and any other charges, real or fictitious, that may be imputed to Diesel power-houses. Maintenance cost of Diesel engines has been the subject of many controversies and discussions. Many engineers still consider that it must necessarily be very high, but some day they will receive a great surprise when they will eventually discover that it is not so. Diesel engines, suitable for railway traction and built from now on, must be capable of running at least 20,000 kiloms. without requiring any major adjustments. On completing this mileage a few days should suffice to do whatever is necessary to make them fit for a further run of 20,000 kiloms., and so on until 150,000 kiloms. is reached, when a general overhaul will be due. What will be the cost of a general overhaul? It will be found considerably less than that required by steam locomotives of equal H.P., and service kilometrage. Any Diesel engine that does not come up to this standard of performance should be scrapped. Before dismissing the subject of Diesel mobile power-houses for suburban train service, I wish to call attention to the large capital expenditure needed for ordinary electrification in the way of distribution system, sub-stations, track equipment, &c., all of which must be provided at the very commencement of electrification on a scale to suit the maximum working capacity of the line, whether the volume of traffic then offered is existent, or merely potentially remote. The maintenance cost of this large equipment is a very appreciable amount, and cannot be ignored in making comparisons between the two systems of traction.

Main Line Traction.

Regarding main line trains, it is only a few days ago that a test run with the Diesel-electric locomotive hauling a passenger train of 591 tons was made. The distance travelled was 120 kiloms. with four intermediate stops. A maximum speed of 98 kiloms. per hour was reached, the running speed of the whole trip averaging 82 kiloms. per hour with a fuel consumption of 3·25 kilos. per train-kilometre. From experience, I find that on equal services the fuel consumption of Diesel-electric locomotives averages in weight between one-fourth to one-fifth that consumed by superheated steam engines using fuel oil. The consumption ratio between fuel oil and coal with our steam services is one of oil to 1·25 of Welsh coal. Practice has shown that the fuel consumption of Diesel engines does not vary to any appreciable extent from one general repair to another. The fuel consumption of the two original power-houses remained practically constant from the time they were put in service until withdrawn for general repairs after having run 125,000 train-kilometres. By that time several pistons had been working without the top rings, due to excessive wear of the grooves on the pistons, into which other rings could no longer be fitted.

The general trend of discussions, comparisons, &c., shows that Diesel traction is now receiving a good deal of attention from the engineering professions. In the final sifting of it all we shall no doubt get to the true facts.

Oil *v.* Steam Locomotives.

In making comparisons between Diesel and steam traction, it is often found that the basis of comparisons is not always correct. Not long ago there came to my notice a most interesting study made on this subject, giving long columns of comparative figures relating to capital and working costs of an assumed large railway. After pondering over these figures for many hours, I was forced to the conclusion that they served no useful purpose, because the figures relating to Diesel traction were merely assumptions and not facts. It is quite useless to compare to-day's cost of steam with that of a Diesel locomotive. In the first case we are dealing with a highly competitive business, in more or less moribund conditions, bolstered up by accepting orders often at ruinous prices. On the other hand, the present-day prices of Diesels merely represent what manufacturers would like to get for their ware, and in no way what would be paid in a competitive market.

Locomotives, in themselves, do not represent the total capital expenditure involved in the power-producing plant of a steam railway; there are other large expenditures in running sheds, land, building tracks, turntables, water supply throughout the system, without which a steam locomotive is useless. These costly adjuncts must be included in the total capital cost of motive power. Of course, as regards railways that have already reached their full expansive capacity, and have spent large sums on sheds, &c., Diesel traction does not offer them the same advantage that it does to other railways which still continue to expand, as is the case with most railways in this country. There is yet another saving to the credit of Diesel, represented by the large amount of money locked up in spare parts stocked at all running sheds. Diesel locomotives carry their own "running shed," whilst the only spares needed consist of about four valves, a couple of big end bearings, and an assortment of other small items. Conditions and environment in which mechanical repairs to steam locomotives are carried out in dark, wet running-shed pits, compare very unfavourably with the nice and well-lit vehicles, with every facility for doing the little amount of running repairs that a Diesel engine requires. Consider how the *morale* of the maintenance staff would be raised by the improved conditions and better work, benefits which cannot be computed in cold figures, but are, nevertheless, great advantages to the general working of a railway. To get at the real truth, facts must be squarely faced, every *pro* and *con* must be carefully scrutinised, and once this is done I have no doubt as to which the final winner will be in this hard-fought contest. Diesel traction no longer needs defence; it is pushing its way forward, and I feel certain that the time is not far distant when no progressive railway executive can afford to ignore its existence, be their railways happily situated near a waterfall or having coal mines on their property. Diesel traction offers many other advantages, besides a reduced fuel cost and the doubling or trebling of the mileage obtainable per working unit. A Diesel locomotive requires no rest days and is easily supplied with fuel and lubricant, which is about all that it needs between periodical revisions at distant dates.

Question of Design.

In the course of time and from experience gained, I have come to several conclusions, amongst which are the following:—It was generally considered, and still is, amongst certain engineers, that Diesel engines required very substantial foundations on which to rest and on which to be secured. Such foundations usually take the form of rigid frames of the steam locomotive type or other similarly built-up structures.

Every part of a Diesel engine is subject to vibrations of various frequencies, which as a rule damp themselves out, provided that the engine is not too rigidly held. The moment restriction of vibrations is introduced in the form of rigid frames troubles occur, either in the engine itself or in other parts of the structure. A rigid frame transmits to the Diesel engine all the shocks that emanate from the rolling of the wheels over the track. These shocks may become very destructive by the gyroscopic effects produced on the gyrating engine shaft and its supports. The safest way out of the difficulty is to give the engine ample freedom by resting it on a common vehicle frame, supported on well sprung bogies. You will notice, when visiting our power-houses, that a person walking along the vehicle causes the body of same to move in unison with each footstep. These power-houses ride very well at all speeds. The main line Diesel-electric locomotive was also built on the same principles of carriage, and at the high speed of 130 kiloms. per hour the riding was very steady. I have found that to obtain good riding qualities the mass and location of the various weights that constitute the locomotive must be considered in relation to the centre of the rotating shaft. I have not yet been able to unravel this intricate problem in all its details, but I think we are getting somewhere near to be able to formulate definite rulings.

It is considered, and supported by reputed trials, that nose-suspended traction motors are unsuitable for high-speed electric locomotives. The alleged defect of this system of drive is that at high speeds the motor wheels of the bogies cause a lateral pressure on the track amounting to as much as 40 per cent. of the static load carried by the wheel, resulting in a destructive effect to the track, apart from the potential danger of derailment. Recently we had the opportunity of testing our main line Diesel locomotive at speeds up to 130 kiloms. per hour, taking curves with the greatest ease at 100 kiloms. per hour that would have been risky at 70 kiloms. with a steam locomotive. The riding is equal to that of a passenger car—in no case did we notice any "nosing" or serious joltings going over points and crossings. That the underhung roller bearing axle-boxes used on this locomotive prevent any undue lateral pressure being exerted on the track, was proved by the absence of signs on the wheel flanges of having rubbed against the rails. This experience is confirmed by a similar experience in connection with large passenger vehicles fitted with these bearings, involving many hundreds of thousands of vehicle kilometres. These results have convinced me that bogie vehicles are by far the best wheeling arrangement for railway locomotives, and it should go far towards cheapening production if the large driving coupled wheels that have become more or less standard with electric locomotives can be avoided. There is also a good deal I should like to tell you regarding design of bogies, motor suspension, &c., which, however, cannot be adequately dealt with in an address.

A 1000 H.P. Diesel-electric group of a total weight of 32 tons can be produced, from which a locomotive on two four-wheel bogies, all motored, of 82 tons total weight can be built. A Diesel-electric locomotive can be made capable of turning its full horse-power into tractive effort from a train speed of 7 kiloms. per hour up to the maximum designed speed; therefore, the 82 tons are barely sufficient to provide the necessary adhesion for the very large tractive force available at very slow speeds; think of the complications in the way of boosters on a steam locomotive in order to obtain similar results; the facility with which any number of Diesel-electric locomotives can be worked automatically by one driver from the leading engine; a number of comparatively small units of 1000 H.P. give more service for capital invested than a series of large units, be they of the twin type or single-motored; the flexibility of this system should appeal to all railway engineers. After all, a 1000 H.P. is not to be despised; it can deal with a 350-ton passenger train at any speed required in this country or haul a 1200-ton cargo train with ease. It might be said that a passenger locomotive could not be used for cargo, or *vice versâ*, to which I would answer that there is not going to be a passenger and cargo Diesel-electric locomotive, but only one locomotive for both services. Here I am somewhat anticipating; in any case, it indicates the lines that are being followed.

The weight of 21 tons on the driving wheels of Diesel-electric locomotives is in no way excessive for bogies with a wheel base of not less than 1·75 the track gauge. The unsprung weight will be about 3 tons or less than the weight of a steam locomotive driving wheel and axle. As far as track is concerned, the 21 tons will cause about the same stresses as a steam locomotive driving wheel with a static load of 18½ tons, remembering that twice in each revolution of the driving wheel the static that it sustains is increased by at least 12 per cent., by the resultant of steam pressure on the piston and the varying angularity of the connecting-rod. On lines where this axle load could not be considered, six-wheeled bogies can be used. I have seen an excellent design of an all-wheels-motored bogie of this type that should give excellent results, and would not be too rigid on curves.

For shunting at yards, depôts or for running light trains, the 500 H.P. and possibly the 700 H.P. may be found useful. However, the most important point is to restrict the number of sizes to a minimum, so that well-tried and tested designs may be manufactured in mass production, and cheaper costs.

THE ROYAL INSTITUTION.

The Christmas lectures of the Royal Institution of Great Britain will be presented by Sir James Jeans, F.R.S., who has chosen for his subject "Through Space and Time." The lectures will begin at 3 p.m. at 21, Albemarle-street, W.1. Lecture I., "Earth and Moon," Thursday, December 28th, 1933; Lecture II., "Moon and Planets," Saturday, December 30th, 1933; Lecture III., "The Sun and its Family," Tuesday, January 2nd, 1934; Lecture IV., "The Nearer Stars," Thursday, January 4th, 1934; Lecture V., "The Further Stars," Saturday, January 6th, 1934; Lecture VI., "The Nebulæ," Tuesday, January 9th, 1934. The subscription for this series of juvenile lectures will be: juveniles (aged 10–16), half-a-guinea; adults (non-members), one guinea.

LAUNCHES AND TRIAL TRIPS.

Arc, steel motor barge; built by Richard Dunston, Ltd., to the order of the Electricity Department of the Leeds Corporation. Oil, engines 50 B.H.P. "Widdop" Diesel; trial trip, November 29th.

Steel barge; built by Henry Scarr, Ltd., Hessle, near Hull; dimensions, 75ft. 6in. by 14ft. 9in. by 7ft.; to carry coal on the Yorkshire waterways; launch, November 29th.

Steam-driven cutter suction dredger; built by Wm. Simons and Co., Ltd., to the order of the Chinese Purchasing Commission, under the direction of Sir J. H. Biles and Co. This dredger is to be used for keeping a clear berth for the Nanking Train Ferry, China. Launched with all machinery on board and steam up, December 1st.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

Schiess - Defries, Dusseldorf, has appointed Schiess-Defries (Gt. Britain), Ltd., of 25, Victoria-street, London, S.W.1, sole representatives in Great Britain for the whole of its interests.

A. C. Wickman, Ltd., Coventry, have been appointed the sole selling agents in Great Britain for the Humphris patent open-fronted and inclinable presses, which are made by Mass Products, Ltd., Newtown, Parkstone, Dorset.

Mr. Archibald J. Boyd has been appointed managing director of Metropolitan-Cammell Carriage, Wagon and Finance Company, Ltd., in succession to Mr. Arthur S. Bailey, O.B.E., who will retire at the end of the present year.

CONTRACTS AND ORDERS.

The Editor is always happy to print short announcements of contracts and orders in this column provided they are sent to him in time to have news value and that they are likely to interest readers.

Merryweather and Sons have received from the Manchester City Council an order for an all-British motor turntable fire escape with all-steel ladder, capable of extension to a height of 100ft.

C. A. Parsons and Co., Ltd., of Newcastle-on-Tyne, have received an order for a large turbo-compressor capable of delivering 900,000 cubic feet of gas per hour at an absolute pressure of 154 lb. per square inch. The compressor will run at 5670 r.p.m. and will be driven by step-up gearing from a steam turbine running at 3300 r.p.m.

Scientific Management.—Progress is being made with the organisation of the Sixth International Congress for Scientific Management, which is to be held in London from July 15th to 18th in 1935. A strong Council, which includes representatives of societies connected with some phase of scientific management, has been formed. The Chairmen of the Committees are Dr. E. F. Armstrong, F.R.S. (Organisation), Sir Henry Fowler (Technical), and Mr. G. R. Freeman, F.C.A. (Finance). Mr. H. Ward, late General Secretary of the National Institute of Industrial Psychology, has been appointed Secretary. Amongst the questions which will be discussed are:—(*a*) Concrete Examples of the Application of Scientific Management to Distribution Problems in Manufacturing, Wholesaling and Retailing; (*b*) Methods of Controlling Production; (*c*) Methods of Selection, Education and Training of *Personnel* Suitable for High Administrative Positions; (*d*) What are the Correct Methods of Inculcating Modern Management Principles and Practices in Large-scale, Medium, and Small Undertakings? What is the *Rôle* of Trade or other Associations in this Field?

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The World's Steel Market.

The situation in the Continental steel markets has improved somewhat of late, and more orders have been received by the works, although these have not been sufficient to establish a sound rate of operation. Amongst the business taken have been orders from the Soviet Government, totalling about 15,000 tons of structural material and plates, of which about 11,000 tons were badly needed orders for thick plates. It is understood plate contracts will be executed by Belgian works, whilst the orders for structural steel will go to French works. Rather more stable exchange rates have resulted in a slight cheapening of Continental steel export prices in sterling, the reduction being about 1s. 6d. Business in Continental steel in the British market has been more active of late, but not on a scale to cause anxiety to British makers. Japanese competition, however, has been felt in India principally in the section of the market which takes the cheaper descriptions of steel supplied by the Continent. It is also reported that there are signs that sellers of Japanese steel are trying to gain an entry into the South African market. In the United States the increasing costs of production have resulted in the announcement of price advances on a wide range of finished steel materials.

Semi-finished Material.

The stringency in this market is noticeably more pronounced, and consumers are becoming nervous regarding the position, not only because of the lack of assurance regarding future supplies, but also in view of the strong tendency for prices to rise. A few months ago British billets could be obtained freely at £5 d/d, and sheet bars at £4 15s. It is not easy now to find sellers willing to accept £5 7s. 6d. and £5 5s. respectively. Many producers are so well supplied with orders that they stand out for £5 10s. to £5 12s. 6d. in the case of billets. Business in sheet bars has improved lately, and this has enabled the makers to advance their quotations; but the variation in the quotations for this material is greater than for billets. In Wales and on the North-East Coast the quotation for sheet bars is £5; but in the Midlands, where considerable supplies are obtained from outside districts, the general price is £5 5s. From all districts, however, the story comes of works being booked up and of delays in deliveries, so that it is not surprising that the volume of business going abroad has been increasing recently. The prices of Continental material also have a strong tendency to advance. The sale of foreign supplies is in the hands of a pool in London composed of representatives of the Continental works, firms which, since the European Steel Cartel adopted its new sales policy some months ago, have ousted the British merchants who formerly handled part of this trade. This organisation considers each transaction upon its merits. This policy has disadvantages as well as advantages. It enables the pool to keep a complete control of the market for foreign semis in Great Britain; but it also promotes much uncertainty amongst consumers, who are never sure of how near to the market price they are buying. The answer is that there is no genuine market price under these conditions and this is certainly true, since consumers report a wide variation. In Wales, for instance, a parcel of sheet bars was sold recently at £4 1s. delivered; in Scotland billets were quoted at £4 17s. 6d.; and in the Midlands sellers claim to have obtained £5 10s. delivered. Lately the quantities offered in the British market have not been large.

The North-East Coast and Yorkshire.

The demand for finished steel materials has not been affected so far by the usual seasonal influences. In fact, in some departments the volume of business has increased instead of showing the usual decline. The heavy engineering trades are making progress, and this is reflected in a better demand for steel materials. Business, however, rests largely upon the home trade demand, and although some expansion is noticeable in exports, any important increase is checked by the operation of high tariffs, quotas, and exchange difficulties. On the North-East Coast the improvement in the shipbuilding industry which has taken place on the Clyde has not yet reached the Tyne and the Tees. S. P. Austin and Sons, of Sunderland, have, however, taken orders for three steamers of about 3000 tons deadweight from Cory Collieries, Ltd., and the ship repairing yards remain busy. The structural engineering shops in this district are well employed, and their demands are reflected in active conditions at the steel works. The position of the latter has also been strengthened by the receipt of an order for 2200 tons of structural steel from the New Zealand Government. The rail department also is busy on an order for tramway rails for the London Transport Board. In Yorkshire many of the works are operating almost at full capacity, whilst the promising nature of the outlook can be gauged by the fact that negotiations between the employers' organisations and the trade unions are in progress regarding work being continued over week-ends. Compared with last year, 10 per cent. more men are now employed in the Sheffield engineering and steel-making industries.

The Midlands and South Wales.

The busy conditions which have ruled in the finished steel department of the Midland industry show no signs of relaxing. Although the structural engineering concerns complain that they have still a certain amount of unemployed plant, conditions in this respect are improving, and some of the recent orders given out should take the place of contracts which are being completed. The re-rollers in particular have heavy order books and their output is largely sold for several weeks ahead. Beyond this they are not anxious to go, as the outlook regarding prices for semis and other raw materials is by no means sure. Quotations for re-rolled small steel bars are fairly steady at £7 5s. to £7 10s., whilst the steel works quote £7 10s. to £8 10s. For export the re-rollers' lowest figure is now £6 15s. f.o.b. Continental sellers continue to offer small steel bars at £6 10s. 6d., d/d Midlands, but although a fair tonnage of orders has been placed the quantities sold have not been so great as might have been expected in view of the margin in favour of the imported material. Continental strip is also quoted at well below the British price at £7 10s. to £8 5s., the home producers quoting £8 5s. to £9 10s. One of the departments which has shown most definite signs of improvement is that providing steel for the collieries, and a fair amount of forward business has been arranged. In South Wales the tin-plate industry, although it is working at a good rate, is suffering from the effects of the depreciated dollar exchange. Not only have the Welsh works lost orders to the Continent by as much as 3s. per box, but buyers on the export markets generally hesitate to place orders until the exchange becomes more stabilised. For a few weeks now the production has been in excess of sales. On the other hand, the steel works in South Wales are busy.

Scotland and Lancashire.

A much improved tone rules in the Scottish steel market since the recent orders for new ships. The total tonnage placed on the Clyde and at Belfast in November, which will provide orders for the Scottish steel works, totalled about 130,000 tons, and it is estimated that 60,000 tons of steel will be required. The constructional engineering firms are not particularly busy, but their position has been improved by some fresh contracts. Export business has been on a poor scale, trading with Canada having suffered the decline always experienced in the winter, and business with other export markets having been checked by the instability of the dollar exchange. The Lancashire market has been fairly active of late and a fair volume of business has been transacted, particularly in the lighter sections of the industry. Business in the machine tool department, for instance, has been on a fairly good scale and hopes are entertained of securing more orders from the Russian Government. It is announced that Mr. R. Greenwood, managing director, and Mr. J. H. Rivers, chief designer, of Craven Bros. (Manchester), Ltd., are visiting Moscow at the invitation of the Soviet Central Engineering Authority to discuss new business. This firm, during the past two years, has completed some large contracts for machine tools for Russia. Conditions at the plate mills has considerably improved on the recent orders for locomotives and other contracts. The demand for sheets, however, is a weak spot, and although trade in galvanised sheets with India has slightly increased of late, there is a considerable amount of unemployed plant in this section of the industry. In the Barrow district it is reported that the steel works have sufficient orders on their books to ensure employment over the first quarter of 1934, and both at Barrow and Workington the mills are rolling rails, billets, slabs, and hoops.

Current Business.

The most important contracts reaching the British iron and steel trade this week were from the Great Western Railway, which placed orders with Guest, Keen and Nettlefolds, Ltd., for 100,000 steel sleepers, weighing 10,500 tons; 10,000 tons of chairs and 25,000 tons of steel rails. An order for 5000 tons of steel rails was also given to the Lancashire Steel Corporation, Ltd. These contracts are part of the Great Western Railway Company's 1934 relaying programme and amount to 50,500 tons of steel. The arrival of 3000 tons of black plates at Port Sarnia, Ontario, from South Wales, marks the beginning of an interesting enterprise on the part of Richard Thomas and Co., Ltd. The intention is to erect a tinning works in Canada to meet American competition in the Dominion tin-plate market. By exporting black plates and tinning them in Canada, the company hopes to obtain the benefit of the Canadian anti-dumping duty. At present no tin-plates are manufactured in the Dominion and under these conditions the Americans are able to secure advantages which they will lose when the plates are made in Canada. The Department of Overseas Trade announces that the following contracts are open for tender:—Brazil, Rio Grande do Sul State Railways, steel superstructures for three railway bridges (Brazil, February 12th); Persia, Municipality of Tehran, supply of plant, including boilers, turbo-alternators, switchboard transformers, and cables for proposed electric power station (Tehran, January 7th); Tokio, H.M. Consul reports that a local firm desires quotations from United Kingdom manufacturers of billets, sheet bars and tube strip; Egypt, Ministry of the Interior, cast iron spigot and socket pipes, double socket couplings, lead wool (Cairo, January 10th); South African Railways and Harbours, train lamps and fittings (Johannesburg, January 15th); supply, delivery and erection of structural steel and ironwork for a cargo shed, Port Elizabeth Harbour (Johannesburg, January 22nd); U.S.A., a firm wishes to get into touch with United Kingdom manufacturers of spring steel plates, 7in. by $7\frac{3}{8}$in. by $\frac{3}{16}$in., and 7in. by $10\frac{1}{4}$in. by $\frac{3}{16}$in., bent to a curve.

Copper and Tin.

The demand for electrolytic copper has improved somewhat over the week, although business is still on a restricted scale. Agreement has not yet been reached upon the American "code," but some of its provisions have been published. According to these another attempt will be made to go direct to consumers and to eliminate the merchants. Whilst Copper Exporters Incorporated (the copper trust) was in existence, this attitude prevailed, and, in the view of many, was partly responsible for the unfortunate position in which the industry finds itself. Lately the policy of the producers has changed, and they have shown a disposition to deal through merchants. The export quotation this week has ruled at 7·70c. to 7·75c., or about £33 5s. to £33 10s. c.i.f. In Europe the most active buyers of electrolytic copper have been Italy and Germany. Trading in the United States also has been dull, and the domestic price has been reduced to 8c. d/d. Business in the London standard market has been quiet on the whole, but a few important buying orders were placed towards the end of the week and, in the poor conditions prevailing, had an effect upon the market disproportionate to their weight. The position in this market has been improved by the liquidation of stale bull accounts, and most of those now in existence are in strong hands. . . . Although business in the tin market has been rather uninteresting, prices registered a moderate advance following the publication of the favourable November statistics. According to Mr. W. H. Gartsen's figures, there was a reduction of 1850 tons in the visible supply, compared with the figures at the end of October, and there was also a reduction of 499 tons in the carry over in the Straits Settlements. At the Arnheim Smelter, however, the carry over increased by 216 tons. One of the most notable features of the statistics was the disappointing deliveries to the United States, which totalled only 3350 tons, compared with 6035 tons in October. The American deliveries for December, however, may be more satisfactory, as American dealers are showing more interest in the market. The Continental demand has been light, but there are indications that more tin is being used in this country.

Lead and Spelter.

Business in lead has been rather less active than in the earlier part of November, but the consumption is probably on a larger scale than at any corresponding season for years past. This is partly due to the fact that building operations, as we have pointed out, have been continued with little interruption later into the winter than usual. The wide contango which rules in the market is due to declarations of Mexican lead which, of course, will go into warehouse. There are already nearly 10,000 tons of lead in bonded warehouse in this country, and in spite of re-exports to Russia last month, there was an increase in these stocks of nearly 300 tons. The cessation of operations at the Mt. Isa mine in Australia has not affected the market, and in view of the heavy stocks in Australia it will probably be a long time before prices will be influenced. . . . Steady conditions have ruled in the spelter market and prices have moved within narrow limits. The industrial demand remains light and is likely to do so until a more sustained improvement manifests itself in the situation in the galvanised sheet market. Consumers are dissatisfied with the position which enables the Empire producers to charge premiums upon the Metal Exchange quotation for their metal. The position is that spelter of foreign origin has to pay a duty of 10 per cent., whilst Empire spelter is allowed free entry. The price quoted on the Metal Exchange does not include the duty which has to be paid by the buyer in the event of his receiving metal in bonded warehouse. This, of course, gives the Empire producers an opportunity of charging a price under the actual figure for bonded spelter and above the Metal Exchange quotation. The Empire producers have always quoted a premium; but originally this was about 2s. 6d. Latterly it has been in the neighbourhood of £1. Within the last few days, however, it has dropped to 15s.

Average Metal Quotations.

The London Metal Exchange official average quotations for November show a decline in all departments of the market excepting tin. This is the fourth month in succession in which the average prices have fallen. The average price for cash tin for November, however, was £2 5s. 8d. and for three months £2 19s. 11d. higher than for October. The fall in copper has been heavier than in other metals, the electrolytic quotation being £3 0s. 8d. lower than for October and wire bars £2 19s. 9d. less. Standard cash copper is £3 1s. 4d. down and three months £3 1s. 11d. The comparative steadiness of lead prices is indicated by the small decline of 5s. 4d. in the average price for "Shipment in the current month," compared with the October quotation, whilst the price for shipment the third following month dropped 6s. 6d., the decline in the mean price being 5s. 11d. There has been a distinct drop in the average price of spelter for November, the quotation for "Shipment in the current month" being 15s. 2d., and for shipment the third month following £1 5s. less than in October, whilst the mean price dropped by £1 5s. 2d. The following are the official average quotations:—

STANDARD COPPER	Cash.. ..	£30	12	6

French Engineering Notes.

(From our own Correspondent in Paris.)

The Surtax.

From usually reliable sources it is affirmed at the moment of writing that it has been decided to suppress the surtax of 15 per cent. on British goods imported into France. A decree to this effect, it is believed, is to be published during the week, when an unfair fiscal imposition which has caused so much friction between the two countries would be definitely removed.* In taking this step the Government has had to override a strongly organised opposition from industries which are interested in maintaining the tax, but, on the other hand, the suppression of the tax was inevitable in view of the disastrous effect which the threatened British reprisals in the form of an additional tax of 21 per cent. on certain French goods would have had on French exporting industries. The Lyons industries, for example, implored the Government to take immediate action in order to avoid their utter ruin. Another factor in influencing the Government to suppress the surtax is the impossibility of applying it to the devaluated dollar, owing to swift reprisals that would have followed from the United States at a time when the French expect to benefit considerably from the repeal of the prohibition law. There now remains the 6 per cent. turnover tax which was instituted by law, and can therefore only be repealed by a Bill which is now before the Chamber of Deputies for that purpose, though there are provisions in the law suppressing the tax under certain conditions. Having been abrogated in the case of Belgium and of some other countries, there would appear to be no reason why it should not be suppressed on British goods. It is, nevertheless, to be hoped that the Bill to repeal the turnover tax will be carried through Parliament without further delay, and thereby remove the only obstacle that stands in the way of a resumption of negotiations for a commercial treaty between the two countries. The whole fiscal system has broken down, and a new trade policy must be inaugurated if the country is to recover its industrial and commercial activity. This can only be done gradually, and French manufacturers are promised that the suppression of the surtax will be accompanied by an extension of import quotas, but that method of restriction will have to be applied with prudence if the Government hopes to succeed in its efforts to put the trade policy of the country on a workable basis.

An Exhibition of Quality.

The holding of an exhibition in the Grand Palais, Paris, with the idea of associating quality with French manufactures is an interesting experiment, and if carried out on the lines proposed by its originator, the President of the Federation of Mechanical Industries, the Salon de la Qualité Française would have been instructive. The Exhibition was intended to produce a reaction against mass production, which has, moreover, already fallen into discredit, and to convince buyers of the quality of French goods by showing examples of craftsmanship in all branches of the manufacturing industries. To this extent it cannot be said that the experiment has entirely succeeded. The Salon de la Qualité Française covers too much ground, and there are few examples of individual crafts. Some metallurgical companies exhibit drop forgings and engineering firms have stands with models of harbours and photographs of bridges and other works; while colliery companies give prominence to domestic composite fuels called " artificial anthracite," or by names suggestive of anthracite. The aircraft and motor car industries are partly represented. The Exhibition is more popular than technically interesting. It had been hoped that the Salon de la Qualité Française would have demonstrated industries in which French artisanship particularly excels and helped in the work of industrial decentralisation which introduced art and quality into essentially French manufactures until small industries suffered from the development of big workshops and factories.

The Industrial Situation.

Financial and economic difficulties are having a depressing effect upon the engineering industries, which see little hope of relief unless something is done to put in hand a programme of public works that will include railway building, bridge construction, and possibly the Trans-Saharan Railway. The engineering industries are endeavouring to get as much of their own work as possible into the new programme, which, nevertheless, has no chance of being put in hand until the country's financial situation has undergone a considerable improvement. Hardly any success has attended the efforts of manufacturers to secure orders abroad, particularly when they are dependent on conditions of reciprocity which this country cannot accept. This was the case with the contract for the erection of a sugar-making plant in the Irish Free State, which a French firm failed to obtain, notwithstanding the backing it received from the French Government. The failure is attributed to the fact that the Government was unable to grant to the Irish Free State a sufficient import quota for agricultural produce, and the order therefore went to a German firm, whose Government is stated to have accepted conditions for the importation of Irish cattle. The situation is becoming extremely complicated when so many countries are inclined to carry the principle of reciprocity to an extreme. Where credits are required to secure foreign contracts, manufacturers can usually obtain from the banks all the facilities they need, but the difficulties with reciprocal exchanges are giving rise to the belief that the system is not without drawbacks. Close attention is given to Turkey, where French manufacturers are well represented and are prepared to offer long-term credits for State contracts, and the negotiations now in progress with the Soviet Government are more complicated because they involve import quotas as well as credits. Meanwhile, the only satisfactory feature is the work given to shipbuilders by the Navy Department, and by some of the shipping companies. Locomotive and wagon builders are still waiting for orders that ought to have been distributed at the beginning of the year.

---

* The decree referred to had not been issued up to the moment of going to press.—Ed. The E.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

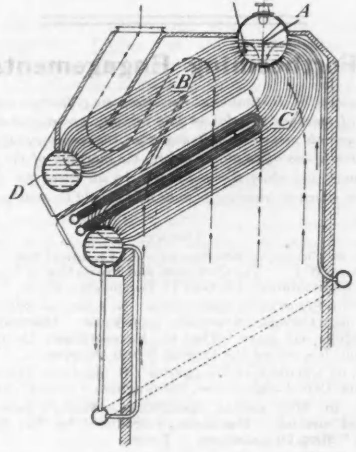
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

396,119. February 5th, 1932.—Water-tube Boilers, A. Williams, 16, Messaline-avenue, Acton, London, W.3.

The inventor points out that, on account of the difference of temperature to which the opposite sides of the drums of a water-tube boiler are subjected, they suffer stresses which limit their practicable length. He aims to overcome this difficulty by providing a system of circulation through the tubes that embraces the whole length of the drums. This is effected by a series of longitudinal and transverse baffles. In the steam drum there is a longitudinal baffle A, which reaches nearly to the ends and separates the heating tubes B from the steam raising tubes C. There are also transverse baffles, both in the steam drum and in the water drum D, which are intended to make a circulation of the water from end to end of the drums positive. The feed-water is injected into the tubes from the steam drum at E.—*August 3rd*, 1933.

Nº396,119

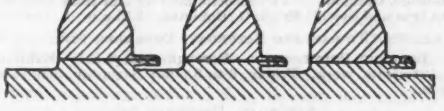


TURBINE-MACHINERY.

400,534. April 27th, 1933.—Turbine Discs, Aktiengesellschaft Brown, Boveri et Cie., Baden, Switzerland.

The discs of steam and/or gas turbines are liable to become loose on their shafts on account of temperature changes causing expansion and contraction. The inventors consequently fix the discs on the shaft by means of thin fins welded together at their extremities. The fins are sufficiently flexible to accommodate the expansion and contraction. The illustration needs no comment.—*October 26th*, 1933.

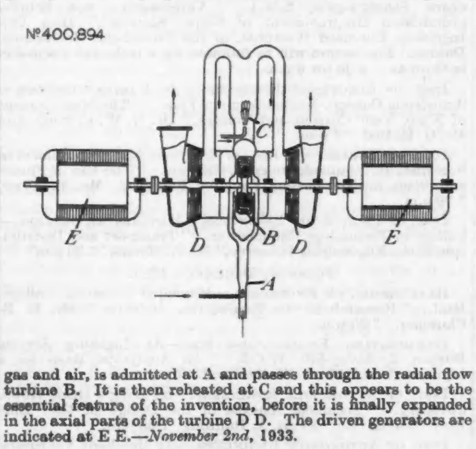
Nº400,534



400,894. July 6th, 1933.—Gas Turbines, Aktiebolaget Milo, Kungsgatan 32, Stockholm, Sweden.

This gas turbine would appear to be designed on the broad principles of the Ljungstrom steam turbine. The working fluid, gas and air, is admitted at A and passes through the radial flow turbine B. It is then reheated at C and this appears to be the essential feature of the invention, before it is finally expanded in the axial parts of the turbine D D. The driven generators are indicated at E E.—*November 2nd*, 1933.

Nº400,894

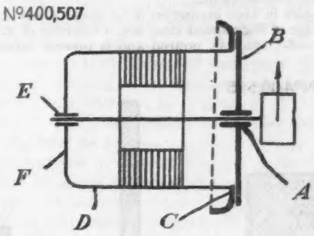


DYNAMOS AND MOTORS.

400,507. March 23rd, 1933.—Sheet Metal Casings for Electric Motors, The Skoda Works, Plzen, 37n, Jungmannova, Prague II, Czechoslovakia.

A sheet metal casing for small and medium size A.C. motors is described in this specification. The driving end bearing A is arranged in a stiff plate B, which is attached to the casing by a dished plate forming a wall C in such a way that turning and bending moments set up by the driving torque are taken up by this plate. The forces which reach the rear feet D through the belt pulley and the bearing E in the base F of the pot-shaped casing are very small, so that the construction of the casing is cheap, as the pot-shaped part is almost entirely free from load and can be constructed from comparatively thin sheet metal.—*October 26th*, 1933.

Nº400,507

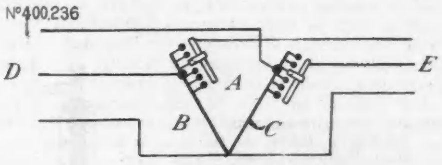


TRANSFORMERS AND CONVERTERS.

400,236. March 18th, 1932.—Electric Transformers, *International General Electric Company, Inc., of* 120, *Broadway, New York, U.S.A.*

In the case of high-system voltages with relatively small outputs, the dimensions of the tap-changing equipment become very considerable in comparison with those of the transformer, and it is correspondingly expensive. Apart from this, however, difficulties are encountered in combining it with the transformer, since with high voltages adequate spacing is necessary between the individual phases. These disadvantages are avoided, according to the invention. A is an auto-transformer in open delta connection with the main windings B and C, which are arranged on two limbs of a three-phase core. The free ends of the windings are provided with tappings. The unregulated system D is permanently connected to three points of the main windings, while the regulated system E is connected with one phase to the vertex of the main windings, and the other two phases are connected through the tappings to the open ends of the main windings. By adjusting corresponding taps on the two windings it is possible to effect a change in voltage on system E, while maintaining the symmetry of the voltage triangle and the phase angle of the transformation unchanged.—*October 18th*, 1933.

Nº400,236

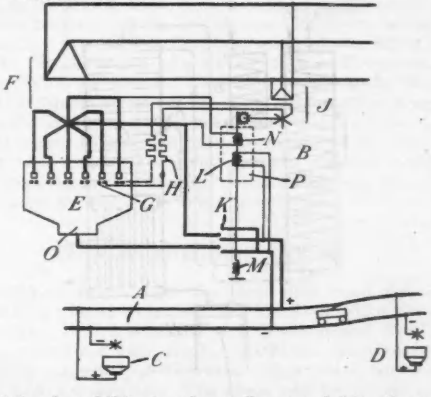


TRAMWAYS AND RAILWAYS.

400,688. May 10th, 1932.—Recovery of Energy in an Electric Current Distributing System, Aktiengesellschaft Brown, Boveri et Cie., of Baden, Switzerland.

A scheme is described in this specification for permitting regeneration on a traction system fed with rectifiers. A is the trolley wire of a railway system, which is fed from mercury vapour valves placed at the sub-stations B C D. The rectifiers in the sub-stations C and D are without grid control. The valve at the sub-station B on the inclined section of the track is to be capable of being used both as a rectifier and as an inverter for the recovery of the braking energy of a train travelling down hill. It is therefore provided with a grid control for enabling the moment of ignition of the anodes or the application of positive or negative potentials to the grids to be controlled. The rectifier and inverter E is connected over the transformer F to the A.C. network. The grids G are fed over the resistances H from the phase-shifting transformer J. K is a change-over switch which is held under control by the relay coil L and the spring M, if the coil N is disregarded. By means of this change-over switch K the cathode O and the neutral point of the secondary winding of the transformer F are connected alternatively to the positive trolley wire or the negative rail of the conducting system of the railway. The change-over switch K and the phase-shifting transformer J are coupled together and are simultaneously operated by the relay P. Normally the change-over switch K occupies the intermediate position shown, the relay coil L and the spring M being suitably balanced. When a train travels down the inclined section and it is desired to recover the energy, the voltage in the trolley wire will increase. Consequently the relay coil L is more strongly excited and the switch K is changed over in opposition to the force of the spring in such a manner that the cathode O is connected to the negative rail and the star point of the transformer F to the positive trolley wire. At the same time the transformer J is displaced and the grid control so adjusted that the valve E acting as an inverter returns the braking energy of the train to the primary network. The magnitude of the return energy can be adjusted and limited, for instance, by the displacement of the phase displacer J, which influences the grid control, being limited by stops, or by a regulator which is dependent on current or voltage. The change over may equally well be effected in accordance with the voltage differences between the alternating and continuous current voltage. The relay P will in this case be provided with an exciter coil N, which is fed by the A.C. voltage in addition to the coil L which is fed by the continuous current voltage, the two coils acting in opposition to one another.—*November 2nd*, 1933.

Nº400,688



MACHINE TOOLS AND SHOP APPLIANCES.

400,565. June 30th, 1933.—**Hacksaw Blades**, The Henry G. Thompson and Son Company, Chapel and Mill Streets, New Haven, Connecticut.

The object of this invention is to make a saw blade with a cutting edge of high-speed steel and a backing of mild steel. A billet of mild steel is poured and is pierced down its length.

Nº400,565

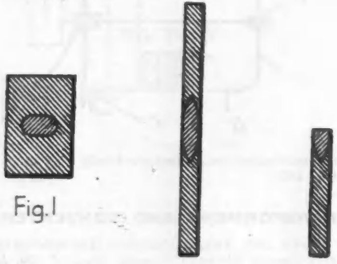


Fig. 1 Fig. 2 Fig. 3

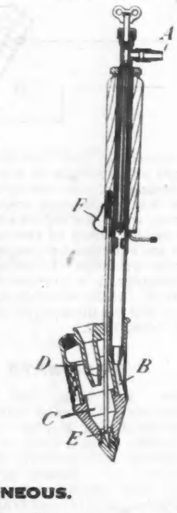
The cavity is filled with high-speed steel as shown in Fig. 1. The billet is then rolled down, as shown in Fig. 2, so that the mild steel is squeezed away from the sides of the high-speed core. The strip is then split along the centre—see Fig. 3—and the saw teeth cut and set in the usual fashion.—*October 26th*, 1933.

399,374. February 6th, 1933.—**Soldering Irons**, A. G. Bain Muirhead, Head of Mine, Denny, Stirlingshire.

This is a gas-heated soldering iron with a reservoir for molten solder. The gas is supplied at A and burns in the annular chamber B round the reservoir C. Solder is fed in through the spout D, which prevents the spilling of the molten solder if the tool is laid down. A valve E, operated by the trigger F, is used to regulate the outflow of the solder.—*October 5th*, 1933.

Nº399,374



MISCELLANEOUS.

399,405. March 11th, 1933.—**The Decomposition of Gas Mixtures with Low Evaporation Point**, Mapag Maschinenfabrik Augsburg-Plattling A.G., and M. Frankl, 234, Ulmerstrasse, Augsburg, Germany.

This invention is concerned with the production of oxygen from atmospheric air. The apparatus comprises the high-pressure pre-cooler A, the low-pressure pre-cooler B operated by evaporating ammonia liquid, the low-pressure after-cooler C, the liquefier D, the evaporator F, the rectifier G, and the expansion engine H. In the pre-cooler A 3 cbm. of high-pressure air at about 200 atm. are cooled by the extracted nitrogen to − 45 deg., also 5 cbm. of low-pressure air compressed to 4 atm. are cooled likewise to − 45 deg. in the pre-cooler B, by evaporating ammonia liquid or any other refrigerating medium. These 5 cbm. of low-pressure air are now cooled in the after-cooler C to − 65 deg. by the extracted nitrogen, expanded in the expansion engine H to 0·2 atm. compression and led into the evaporator F at − 120 deg. in order to evaporate the liquid rectification-oxygen (1·75 cbm.) by sensible heat supply, whereby this air is cooled to − 180 deg. Following this, this air is now led through K into the rectifier G, in order to enrich the wash liquid (2·75 cbm.) to 50 per cent. O_2 content. The further rectification of the wash liquid to the desired O_2 content then takes place in the lower part of the rectifier and is effected by the evaporating rectification-oxygen (1·75 cbm.). Since the quantity of liquid amounts to 2·75 cbm., 1 cbm. O_2 can be withdrawn from the apparatus and carried away. The 3 cbm. of high-pressure air are led out of the pre-cooler A to the liquefier D and there completely liquefied by the extracted nitrogen (7 cbm.) and after-cooled to − 190 deg., in order then to be poured in at the top of the rectifier. Of the 3 cbm. of liquefied high-pressure air, about 0·25 cbm. evaporate by expansion from 200 atm. to the atmospheric pressure of distillation, so that still 2·75 cbm. remain as wash liquid. This new process, it is claimed, possesses the great advanatage of low-pressure operation in the expansion engine and a very simple and cheap construction of the evaporator of the separating column, since this has to withstand, on both sides, only atmospheric pressure and operates at a temperature difference of $182 - \frac{130+180}{2} = 27$ deg., whereas in all other cases only 3–5 deg. are available. The dimensions of the evaporating surface may therefore be considerably smaller. If the liquid oxygen obtained is evaporated in heat exchange relation with high-pressure air, the major portion of the refrigeration is recovered. The installation has now only to make up the refrigeration losses. For that the pressure of the high-pressure air can be considerably reduced and the refrigeration performance of the expansion engine can be cut out. Since 1 cbm. of wash liquid is now produced by the evaporated oxygen, only 2 cbm. of high-pressure air need be liquefied in the apparatus. The refrigeration of the nitrogen is then sufficient to cool to about − 120 deg. the air blown in which is intended for the evporation by sensible heat. If the oxygen is withdrawn from the apparatus in gaseous form, then instead of 1·75 cbm., 2·75 cbm. oxygen must be evaporated in the separator. For this purpose the air for effecting evaporation need only be cooled to about − 80 deg. Since, when withdrawing oxygen in gaseous form, its refrigeration—that is, the refrigeration of the high boiling component—can also serve for cooling the air to be separated, cooling to this temperature without the aid of an expansion engine is possible.—*October 5th*, 1933.

WEDNESDAY, DECEMBER 13TH.

Belfast Assoc. of Engineers.—Queen's Hotel, Belfast "Cement Manufacture," Mr. A. Tindal. 8 p.m.

Inst. of Civil Engineers.—Great George-street, S.W.1. Discussion, "The Control of the Generation of Electricity from a Large Number of Interconnected Stations to Obtain the Maximum Aggregate Efficiency," Mr. J. D. Peattie. 6 p.m.

Inst. of Engineers-in-Charge.—St. Bride Institute, Fleet-street, E.C.4. "Gas and Coke-fired Boilers for Central Heating and Domestic Water Heating," Mr. S. Adam. 7.30 p.m.

Inst. of Production Engineers: Coventry Section.—King's Head Hotel, Coventry. "The Control of Quality in Hardening and Heat Treatment Processes," Mr. H. H. Beeny. 7.30 p.m.

Inst. of Production Engineers: Luton Section.—Castle-street Hall, Luton. "Modern Methods of Inspection," Mr. M. C. Park. 7.30 p.m.

Inst. of Structural Engineers: Lancashire and Cheshire Branch.—At College of Technology, Manchester. "The Influence of Creep on the Modula Ratios and Working Stresses to be used in Reinforced Concrete," Dr. W. H. Glanville. 7 p.m.

Inst. of Welding Engineers.—At the Inst. of Mechanical Engineers, Storey's-gate, London, S.W.1. "Pressure Booster Installations for Acetylene Distribution for Welding," Mr. C. S. Milne. 7.45 p.m.

Newcomen Soc.—At Science Museum, S.W.7. "Charles Babbage and his Difference Engines," Mr. L. H. Dudley Buxton. 5.30 p.m.

N. East Coast Inst. of Engineers and Shipbuilders: Graduates.—Bolbec Hall, Newcastle-upon-Tyne. "Safety in Factories," Mr. J. Leslie Hobson. 7.15 p.m.

Royal Soc. of Arts.—John-street, Adelphi, W.C.2. "The Art Schools and Industry," Mr. Harold W. Sanderson, 8 p.m.

Soc. of Glass Technology: London Section.—At Old Bell Restaurant, Holborn. Annual dinner. 7 p.m.

Television Soc.—University College, Gower-street, W.C.1. "Electro-optics in Television," Mr. L. M. Myers. 7 p.m.

THURSDAY, DECEMBER 14TH.

Inst. of Civil Engineers: Birmingham and District Assoc.—Queen's Hotel, Birmingham. Annual dinner. Reception, 6.30 p.m.; dinner, 7 p.m.

Inst. of Engineering Inspection.—At Junior Inst. of Engineers, 39, Victoria-street, Westminster, London, S.W.1. "The Manufacture and Inspection of Taps," illustrated by exhibits, Mr. L. G. J. Henshaw and Mr. A. Downie. 5.30 p.m.

Inst. of Marine Engineers: Junior Section.—The Minories, E.C.3. Film display, I., "The River Tyne," II., "The World of Machinery at the Leipzig Engineering Fair." 7 p.m.

Inst. of Structural Engineers.—10, Upper Belgrave-street, S.W.1. "Rigid Frame Bridges in Reinforced Concrete," Mr. A. P. Mason. 6.30 p.m.

FRIDAY, DECEMBER 15TH.

Inst. of Chemistry.—30, Russell-square, W.C.1. Fifth S. M. Gluckstein Memorial Lecture. "The Chemist as a Directing Force in Industry," Dr. Herbert Levinstein. 8 p.m.

Inst. of Electrical Engineers: N. Eastern Centre.—Grand Assembly Rooms, Barras Bridge, Newcastle-upon-Tyne. Annual dinner and dance. 7 for 7.30 p.m.

Inst. of Mechanical Engineers.—Storey's-gate, S.W.1. Discussion, "Heat Transfer between Metal Pipes and a Stream of Air," Dr. Ezer Griffiths and Mr. J. W. Awbery. 6 p.m.

Inst. of Structural Engineers: Midland Counties Branch.—At James Watt Memorial Inst., Birmingham. Discussion on "Welded Structures," 7 p.m.

Inst. of Structural Engineers: Western Counties Branch.—At Merchant Venturers' Technical College, Bristol. "Reinforced Concrete Bridges," Mr. J. T. Gueritte. 7.15 p.m.

Junior Inst. of Engineers.—39, Victoria-street, S.W.1. "General Principles Governing Cable Network, Design and Maintenance in Large Towns," Mr. E. W. Carline Day. 8.30 p.m.

N. East Coast Inst. of Engineers and Shipbuilders.—Mining Inst., Newcastle-upon-Tyne. "Modern Practice in Ships' Steering Gear," Messrs. W. J. Paulin and W. Spencer Paulin. 6 p.m.

Railway Club.—Broad-street Station Restaurant, E.C. Annual dinner.

Royal Inst. of Great Britain.—21, Albemarle-street, W.1. Discourse, "Industrial Research: A Business Man's View," Mr. Kenneth Lee. 9 p.m.

SATURDAY, DECEMBER 16TH.

Inst. of Electrical Engineers: N. Midland Students.—Visit to Messrs. Marshall, Kay and Marshall, Dewsbury. 3 p.m.

Inst. of Engineers-in-Charge.—Visit Express Dairy Company's Research Laboratories, Claremont-road, Cricklewood, N.W.2. 2.30 p.m.

Manchester Assoc. of Engineers.—At College of Technology, Manchester. Conversazione and dance. Reception 6.45 p.m.

Sheffield Metallurgical Assoc.—198, West-street, Sheffield. Young people's party. 3.30 p.m.

MONDAY, DECEMBER 18TH.

Inst. of Automobile Engineers.—At Inst. of Engineers and Shipbuilders, 39, Elmbank-crescent, Glasgow. "Technical Aspects of the Design of the 'Blue Bird' Racing Car," Mr. R. A. Railton. 7.30 p.m.

TUESDAY, DECEMBER 19TH.

Inst. of Engineers and Shipbuilders in Scotland.—39, Elmbank-crescent, Glasgow, C.2. "Mechanical Methods of Solution of Stresses in Frames," Dr. C. H. Lobban. 7.30 p.m.

WEDNESDAY, DECEMBER 20TH.

Inst. of Automobile Engineers.—At Engineers' Club, Albert-square, Manchester. "Repairs," Mr. J. Dent. 7 p.m.

Inst. of Engineers and Shipbuilders in Scotland.—Gordon Restaurant, Gordon-street, Glasgow. Luncheon. 1 p.m.

A Seven-Day Journal

London's Newest Hotel.

The new Cumberland Hotel at Marble Arch, built for the service of J. Lyons and Co., Ltd., was visited by the King and Queen on Sunday last, and was officially opened on Tuesday, December 12th. Its construction was supervised by the owners' engineering and electrical engineering departments, and it is noteworthy not alone for its size and modern equipment, but for the engineering side, which contains many features of technical interest. In its structure there is one of the heaviest girders built by Dorman, Long and Co., Ltd., which has a span of 68ft., a width of 2ft. 4in., a depth of 10ft. 4in., and weighs close upon 100 tons. The total weight of the steelwork is over 17,000 tons. In order to meet the steam requirements of the hotel, including heating, cooking, and thermal storage, there are five Thompson dryback boilers, oil-fired on the Clyde system, which furnish steam at 205 lb. per square inch, which is reduced to 100 lb. and lower pressures for the various services. The air-conditioning and refrigerating plant, installed by the Carrier Engineering Company, Ltd., includes both steam turbine and electrically driven refrigerating compressors and fans. Hot water is stored in three large calorifiers, with a total capacity of 20,000 gallons. In addition to the main refrigerating compressor above referred to, there are a large number of smaller Hallmark compressors for domestic use. The engineering equipment of this modern hotel, comprising public rooms and 1000 bedrooms, is in every way comparable with that of a large liner.

Foreign Capital in Poland.

The President of Poland has just issued an ordinance to encourage private enterprise and stimulate the investment of further foreign capital in the development of the electrification of the country. According to the *Polska Gospodarcza* (the Official Economic Journal), at the beginning of 1933, there were in existence in Poland, twenty-two companies which had been formed for the purpose of carrying out electricity supply works, and in these companies the share of foreign capital amounted to 142,000,000 zlotys, or 75·5 per cent. of the aggregate share capital of these companies. The first place in this respect is occupied by Belgian capital, with 58·7 million zlotys. One of these companies—the Société d'Enterprises Electriques en Pologne, which has seven subsidiary supply companies in Poland—has just paid a dividend of 16 per cent. for the past year on a share capital of 40,000,000f. The second position from the capital investment point of view is held by Germany with 50,000,000 zlotys. France comes third with 17·2 million zlotys, Switzerland fourth with 8·1 millions, and England fifth with 6·2 millions, while the small balance is in the hands of other countries. Under the new ordinance the Government expresses the hope that foreign capitalists will now take a larger share than hitherto in the work of electrifying the country, and in this direction the State, under definite conditions, will grant facilities in the matter of taxation.

A New London Airport.

For some time past, Gatwick Aerodrome has been used as a reserve aerodrome in foggy weather. It is now to be extended with the object of making it a leading London commercial airport. A syndicate, headed by Mr. A. C. M. Jackaman, is in charge of the new development scheme, which, when completed, will make of the present aerodrome a high-speed airport capable of serving London in all weathers with the minimum of delay in the connections from the terminal aerodrome to Central London. It is pointed out in this connection that the Southern Railway electric train system will enable passengers to reach London in thirty-six minutes, which is quicker than is generally possible by road from Croydon, especially in foggy weather. The high-speed traffic will be catered for by providing a landing surface with a clear run of half a mile in any direction, while the aerodrome is to be equipped with beam wireless systems, including a wireless beacon with a vertical beam, which will operate in conjunction with exceptionally accurate altimeters in the aeroplanes, designed to read to within 10ft. The new aerodrome will be entirely devoted to commercial flying, and there will be no private flying club. The new buildings will include a control tower, and sheds for housing the machines. The Southern Railway Company's Gatwick racecourse station, which is particularly well laid out, adjoins the aerodrome.

Quay Extension at Newcastle.

On Monday, December 11th, Mr. Walter Runciman, President of the Board of Trade, officially opened a quay extension at Newcastle-upon-Tyne, which was begun in February, 1931, under the direction and control of the City Engineer and has now been completed at a cost of about £87,000. The new quay adds 870ft. to the existing structure and provides a water depth of 35ft. at low tide. The reinforced concrete superstructure has a width of 44ft. and the depth from quay deck to the dredged level is 52ft., sites being provided for transit sheds, railways, and roadways at the back of the quay. The double line of rails at the front and rear leaves 100ft. for the transit sheds, which are to be erected later. At the back of the quay is a 36ft. wide reinforced concrete road with a 5ft. footpath. The quay itself has been built for a distributed load of 10 cwt. per square foot, and a 30-ton electric travelling crane. The contractors for the reinforced concrete work, the laying of the railway and crane tracks, and other work were Robert McAlpine and Sons (Newcastle-on-Tyne), Ltd., with L. G. Mouchel and Partners, Ltd., of Westminster. The preliminary earthwork, the demolition of property, and similar activities gave employment to Corporation workers.

A New High-Speed Monoplane.

On Saturday, December 9th, in the course of demonstration flights of Airspeed Courier six-passenger monoplanes piloted by Sir Alan Cobham, Mr. A. L. T. Naish and Mr. Neville Slack, speeds ranging from 160 to 170 miles per hour were recorded. The new monoplane, which will shortly be demonstrated in this country, on the Continent, in South America, and in India, was designed by Messrs. H. E. Tiltman and S. Norway, of Airspeed, Ltd., Portsmouth, in order to meet the demand for a high-speed passenger-carrying machine which will be economical alike in running and maintenance costs. A feature of the design is the use of the patented "Retractor" undercarriage, which draws the wheels into recesses in the wings when in flight, and drops them into landing position when required. The operation only takes nine seconds to withdraw and 2½ seconds to drop the wheels and it is effected hydraulically. It is said to reduce head resistance and to add 30 to 35 miles per hour to the cruising speed of the machine. For overseas service a 260 B.H.P. Armstrong-Siddeley "Cheetah" engine, giving a top speed of 170 and a cruising speed of 150 miles per hour, is fitted, while for British flying conditions an Armstrong-Siddeley "Lynx" engine of 240 B.H.P. is used, giving a top speed of 160 and a cruising speed of 140 miles per hour. With either engine the landing speed is about 50 miles per hour. The main dimensions of the monoplane are :—Span, 47ft.; length, 28ft. 6in.; and height, 8ft. 9in. On Saturday the conditions were far from ideal, but a take-off of 120 yards with a climb to 10,000ft. in twelve minutes with a 3500 lb. load was recorded. The petrol consumption is about 10·5 gallons per hour and the normal range is 700 miles with 840 miles using a special gravity tank.

The Chemical Constitution of Coal.

A report No. 37, just issued by the Fuel Research Station of the Department of Scientific and Industrial Research, and obtainable from the Stationery Office, deals with the action of solvents on coal. It points out that although coal has been our most important asset for centuries, far too little is known about its chemical constitution. As long as coal was mainly utilised by burning it in its raw state a knowledge of its chemical constitution was not necessary. The outlook upon coal, however, the report points out, is rapidly changing. It is coming to be regarded no longer simply as a fuel, but as a raw material for the manufacture of coke, gas and oil, and innumerable chemical products. Looked at from this point of view, a more complete knowledge of its chemical constitution is assuming increasing importance. Coal is so complex that precise information regarding its fundamental constitution is very difficult to obtain. The changes the coal substance undergoes under the application of heat or powerful reagents are usually so profound and complicated that only very limited conclusions can be drawn from these usual methods of chemical analysis. The most promising method appears to be that dealt with in the report, in which the coal substance is dissolved in a succession or combination of solvents in the hope of isolating definite identifiable chemical compounds. The report includes a complete summary of the whole and widely scattered literature relating to the action of solvents on coal—the experimental results and conclusions contained in it being in most cases set out in some detail. A description is also given of hydrogenation experiments on coals carried out with the object of gaining information on the constitution of coal and a better understanding of the mechanism of the hydrogenation process.

Road and Rail.

The introductory report which has recently been submitted by the Committee of Independent Experts to the International Chamber of Commerce draws attention to the international importance of the road and rail problem and emphasises the need for uniformity in the methods employed in attacking it in the various countries. It deals in the first part with the relationships between the State and railways and the State and motor transport, and concludes that unrestricted competition would inevitably lead to a loss all round. The case of a re-established monopoly of road transport is then discussed and is followed by an examination of possible methods of dealing with the road and rail problem. These are divided into three categories : firstly, a complete monopolisation of both forms of transport in a single organisation ; secondly, a system of competitive monopolies ; and thirdly, a system of co-ordinated competition. The Committee does not make any recommendations as to the adoption of one or other of the alternatives reviewed beyond general agreement on the impossibility of a system of unrestricted competition. It believes rather that for the present it has fulfilled its mission by studying objectively and submitting for consideration the different policies which are being or might be adopted.

The Flow of Thames Water.

According to a statement made by Lord Desborough at the Thames Conservancy meeting, held on Monday, December 11th, the flow of water in the river Thames was smaller in November and early December than it has been for twelve years. The average flow for last month measured at Teddington was 539 million gallons, compared with the normal rate of 1486 million gallons. Since the end of November the flow has still further decreased, reaching an average of 400 million gallons a day, against the normal December flow of 2073 million gallons. From official sources it is stated that a good deal of rain will still be required to fill up the chalk springs, and the widespread frost is greatly restricting the flow of surface water all over the Thames basin. Although the flow is seriously reduced, there seems to be no likelihood of a shortage of water within the London area. The Metropolitan Water Board is drawing about 180 million gallons of water from the Thames above Teddington daily and the Board's storage reservoirs are well filled, while the linked-up pipe lines of the Board have enabled it to supply East London adequately in spite of the failure of the Lea River.

Tramp Shipping.

At the end of last week two important pronouncements on the state of British shipping were made. The Council of the Chamber of Shipping passed a resolution setting forth its agreement with the report of the Tramp Shipping Committee with regard to the causes of the present position, and recommended that the Government be asked to grant a temporary subsidy with the object of equalising the advantages of foreign competitors secured by subsidies, depreciated currencies, and lower wage costs. The Council urged the grant of a temporary subsidy which would cost about £3,000 000 per year. It was further recommended by the Council that the Government should be asked to intensify its efforts to promote a trade group of nations willing to trade on a reciprocal basis of equality of treatment, but that defensive measures should not be overlooked, A memorandum issued by the Liverpool Steamship Owners' Association endorses the view of the Chamber of Shipping that a temporary subsidy might receive the consideration of the Government, but the Association remains opposed to measures of flag discrimination and reservation in the coasting inter-Empire and world trades, believing that such measures would defeat the maintenance of the British merchant navy, which primarily depends on the restoration of the world's trade. In the course of a speech made in Newcastle-upon-Tyne on Monday last, December 11th, Mr. Walter Runciman referred to the Chamber of Shipping appeal. While assuring those present that the Government would lend a ready ear, he expressed the hope that those who were to investigate the position would not work on the assumption that a simple way out of the difficulty was to be found in subsidies.

New Shipbuilding Orders.

Several orders, both for large and small ships, have been placed within the last few days. The Blue Star Line, Ltd., has placed with Harland and Wolff, Ltd., orders for two 515ft., 12,000-ton deadweight carrying capacity, refrigerated cargo ships for its New Zealand services. The ships will be propelled by ten-cylinder, four-stroke, Harland-B. & W., motors designed to give a speed of about 16 knots. On the Clyde, Scott's Shipbuilding and Engineering Company, Ltd., of Greenock, is to build a passenger and cargo motorship for London owners, Smaller ships include three motor-driven ferry boats for Clyde service to be built by Barclay, Curle and Co., Ltd., and engined by Glennifer Engines, Ltd, A motor tug for War Office target-towing service is to be built by Harland and Wolff, Ltd,, at Govan, and engined at the company's Finnieston works. The most important order of the week was undoubtedly the placing of the new Orient liner with Vickers-Armstrongs, Ltd., of Barrow-in-Furness, The new steamer will be a development of the design of the "Orontes," the latest 20,000-ton liner built by Vickers-Armstrongs for the Orient Steam Navigation Company, Ltd., and will be slightly larger than that ship.

Vertical-Lift Drawbridges.

By E. E. R. TRATMAN.

No. II.

(Concluded from page 564, December 8th.)

Lever-operated Lift Bridges.

In the first article only cable operation of lift bridges was considered, except that the quoted statement by Mr. Hovey contained mention of "mechanical links." Lift bridges in which cables are dispensed with are of interest for their operating features, but only a few bridges of this type have been built. The general arrangement is that on each tower is mounted a pair of pivoted trusses acting as horizontal rocking levers or "walking beams." Their outer ends are connected to the trusses of the lift, while the rear or shore ends carry counterweights.

In the Strobel design, the levers are normally tilted downwards, with their outer ends connected directly to the lift span by pivot pins. To compensate for the forward horizontal movement of the end of each lever, caused by its radial or circular path of travel, the connecting pin is carried in a roller which rides against the bottom of a short beam above the chord of the truss. An alternative arrangement is to provide horizontal travel for the trunnion bearings on the top of the tower, so that the bearing rolls back as the lever swings upward and the connection of lever to truss has thus a practically vertical path. In the Strauss design, the rocking levers have ordinary fixed trunnion bearings, but the levers are connected to the lift span through the medium of vertical links or hangers. These are pivoted to the levers and to the lift span, and their movement compensates for the lateral movement or swing of the levers.

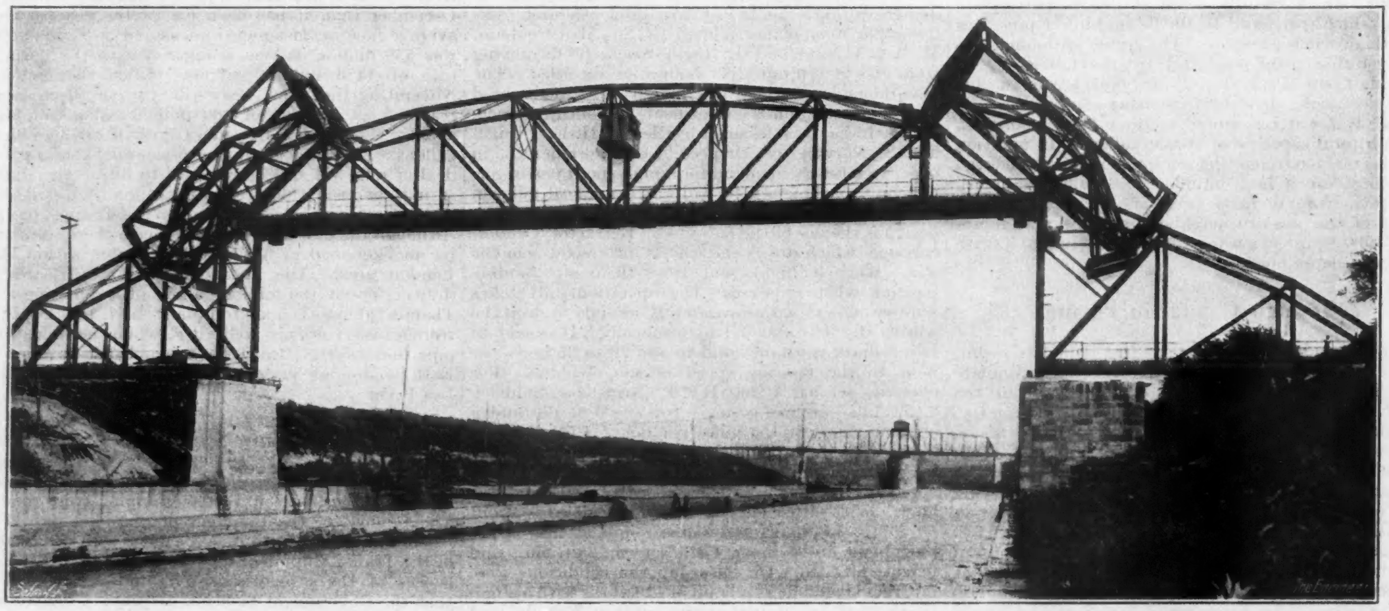

Fig. 9—Lever-Operated Lift Bridge, Louisville, U.S.A.

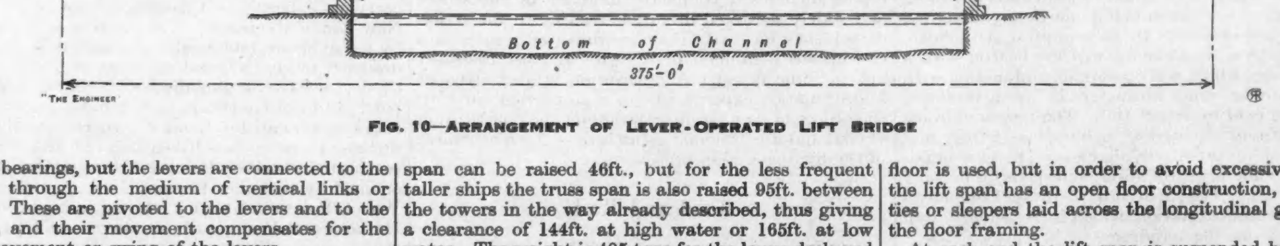

Fig. 10—Arrangement of Lever-Operated Lift Bridge

Both the Strobel and Strauss designs have the same method of operation, a power-driven pinion at each corner of the lift span gearing with a vertical rack on the face or the outer side of the column of the tower. A typical design, shown in Figs. 9 and 10, is a road bridge of the Strauss pattern built across the canal at Louisville, U.S.A. This bridge has a span of 210ft. and a vertical travel of 40ft. In a modification of the Strauss design the levers are eliminated and the lift span is suspended by cables in the usual way. There are, however, no operating cables, motor-driven pinions on extensions of the bottom chords of the trusses gearing with vertical racks on the tower posts. This arrangement is used on a 259ft. lift span of the highway bridge over the Illinois River at Pekin, U.S.A.

Multiple-lift Bridges.

A special application of the cable-operated lift bridge system is for double-decked bridges. A highway viaduct at Kansas City crosses the Missouri River by a high-level fixed span 428ft. long, of the through truss type. From this is suspended a 750-ton lower deck for railway lines at the ground level. This deck can be pulled up 43ft. above its normal position, or to the bottom of the fixed high-level span, giving a clear headway of 65ft. above the water. A bridge over the Willamette River at Portland has a 220ft. through truss lift span carrying a railway line, and below this is suspended a highway bridge which gives normally a headroom of 5ft. at high water or 26ft. at low water. To accommodate small craft the highway span can be raised 46ft., but for the less frequent taller ships the truss span is also raised 95ft. between the towers in the way already described, thus giving a clearance of 144ft. at high water or 165ft. at low water. The weight is 485 tons for the lower deck and 1900 tons for the truss span, a total of 2385 tons.

In both these bridges the method of raising the lower deck embodies the multiple-cable arrangement devised by Mr. Whipple some sixty years ago for his Erie Canal bridges, already mentioned. The lower span is simply a deck or floor framing, having at each panel point a hanger rod which telescopes in the corresponding post of the truss span above. When the deck is in its lowered position live load is taken by pins in the tops of the hanger rods, these pins being seated in saddles in the bottom chord of the truss and locked against vertical movement. Two cables attached to the top of each hanger pass up through the truss posts to sheaves in the upper part of the truss span, thence horizontally to the ends of the span, under guide sheaves at the ends, and up the towers to the head sheaves and counterweights. Each panel point is counterweighted independently.

Operation is effected by applying power through gearing to the guide sheaves at the ends of the truss span. For the operation of the upper or truss span in the Portland bridge the system is similar to that of ordinary vertical-lift bridges, as illustrated in Fig. 7 (*ante*) and already described.

Hackensack River Bridge.

To come back to the more typical cable-operated lift bridges, a specific example is the Hackensack River Bridge of the Delaware, Lackawanna and Western Railroad, shown in Fig. 11. Here the lift span is 198ft. long between end bearings, and its towers form short flanking spans of 85ft., instead of being built upon longer approach spans, as in many other bridges of this type. These towers are 168ft. high from top of pier to centre of cable sheaves, and the bridge has a vertical travel of 100ft., giving a maximum clearance of 140ft. The operator's house is in one of the towers, while the machinery house is at the centre of the lift span, above the railway lines. The bridge carries three lines of rails, spaced 13ft. between centres, and the trusses are therefore spaced 45ft. between centres. On the fixed spans a concrete floor is used, but in order to avoid excessive weight the lift span has an open floor construction, with the ties or sleepers laid across the longitudinal girders of the floor framing.

At each end the lift span is suspended by thirty-two cables, sixteen at each corner. These cables are of plough steel, 2in. in diameter, with an ultimate strength of 298,000 lb. per square inch. They are attached to transverse lifting girders riveted between the vertical end posts of the trusses. Threaded eyebolts in the attachments provide for the adjustment of length of individual cables, as shown in Fig. 12.

At the tops of the towers the cables pass over sheaves 13ft. in diameter and thence down to the two 610-ton counterweights.

Electrically operated gearing in the machinery house drives four drums, two on each side, as in Figs. 3 (*ante*) and 11, from which the 1in. operating cables lead to both ends of the span. There are two up-haul and two down-haul cables in each direction on each side of the bridge, making a total of sixteen operating cables. Their ultimate strength is 81,000 lb. From the guide sheaves at the ends of the span the up-haul cables lead vertically up to the projecting platforms at the tops of the towers, where they are coupled to threaded eyebolts which provide for adjustment of length. Similarly, the down-haul cables lead vertically downward to adjustable attachments or take-ups at the feet of the towers. These cables, attachments, and take-ups are shown in Fig. 12. Indicators in the operating house are connected to the moving span by ¾in. phosphor-bronze tiller ropes.

Current for the motors is taken from 1in. cables suspended between the tops of the towers, the connection being made by a vertical rocking frame or pantograph pivoted on the roof of the machinery house. The cables are attached to one tower, pass under a contact sheave on the rocking frame, and then over sheaves in the opposite tower, where they are connected to small counterweights, as shown in Fig. 11. The pivoting of the frame permits it to swing freely as the contact sheaves ride on the cables in the opening and closing of the bridge. Cables for signals and other purposes are suspended from brackets on the sides of the towers, as indicated on the end elevation in Fig. 11.

FIG. 13—CABLE ATTACHMENTS TO COUNTERWEIGHT—DES PLAINES RIVER BRIDGE

DES PLAINES RIVER BRIDGE.

In the bridge of the Chicago, Rock Island and Pacific Railroad over the Des Plaines River, at Joliet (Fig. 14), the hoisting arrangement is of the direct-lift type, the suspension or counterweight cables serving also as operating cables by the application of power to the head sheaves on the towers. This system was first used in the White River bridge in 1927, as noted already. Owing to a skew of 38 deg. 46 min., the length of span in the Des Plaines River bridge is 298ft. 9in. between end bearings to give a clear width of 152ft. between the piers. The towers are built as integral parts of the approach truss spans, 100ft. and 150ft. long. At present the height of lift is 50ft., but as a greater clearance above the water may be required later, the towers are so designed as to permit of separating them from the upper chords of the trusses, the tower proper being then raised by jacking and supported while two additional bays, each 25ft. high, are built upon the trusses. In this way the height of lift will be increased to 100ft.

As in the Hackensack River bridge, the cables are attached to lifting girders between the end posts of the trusses of the lift span, as indicated by the end elevation in Fig. 14. These are double-web plate girders, each web being a ½in. plate 6ft. deep, with an outside flange angle, 6in. by 6in. at top and bottom. A similar girder forms the top of the steel frame of each counterweight, as shown in Fig. 13. This frame or box is filled with and embedded in concrete, and has pockets for blocks to adjust the weight. These blocks are of concrete loaded with steel punchings. Each is 15in. by 20in. and 13in. deep, weighing about 440 lb. The moving span weighs 1235 tons, and the two counterweights total the same weight, consisting of 1000 tons of concrete, 116 tons of structural steel, 75 tons of steel rails, and 44 tons of adjustment blocks.

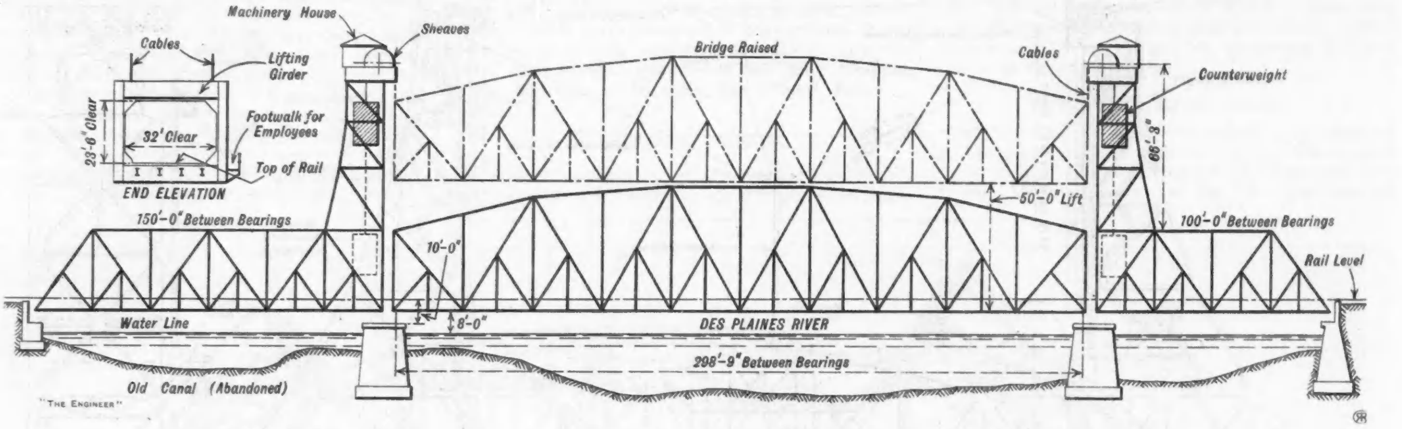

FIG. 14—DES PLAINES RIVER BRIDGE OF THE CHICAGO, ROCK ISLAND AND PACIFIC RAILROAD

A distinctive feature of this bridge is that no equalising device is used to maintain uniform loads on the cables. As a rule, groups of cables have been attached to equalising beams, which, in turn, are connected to the lifting girders or the counterweights by a single pin for each group. The hydraulic equalising device already described is expensive, though effective in operation. For the Des Plaines River bridge, all the cables were cut to exact length while subject to a stress equal to 2 per cent. of the ultimate strength. While being measured, the cable was supported along its entire length, thus preventing any sag or deflection. It was held by the designing engineers that under modern methods of cable manufacture, prestressed cables could be obtained so close to the exact length that the difference in tension in the individual cables of a group of cables under full operating load would be negligible in comparison with the total strength of each cable.

For operating and balancing the bridge, there are sixty-four cables, 2¼in. in diameter, sixteen at each corner of the span. They pass over four sheaves on the towers, 12ft. 9in. in diameter on the pitch line of the cable grooves. Each sheave is grooved to receive sixteen cables. The end sockets of the cables are secured by 4½in. pins to connection plates which lie between the webs of the lifting girder, to which they are connected by a pair of 10in. pins. All the sixteen cables lie side by side, except that a little above the lifting girder and the counterweight a spreader block separates them into two groups for the more convenient and compact arrangement of the cable attachments.

The simple arrangement of the operating machinery for the direct-lift hoisting system of the Des Plaines River bridge is shown clearly in Fig. 15. On each tower are two 75 H.P. motors, both driving through flexible couplings upon the first shaft of a triple-reduction gear with ratio of 91 to 1. This gear, in turn, drives through cast steel couplings an 8in. main shaft carrying two main or operating pinions, each of which engages with a circular rack bolted on the face of a cable sheave. The pitch diameter is 20·37in. for the pinion—with sixteen teeth—and 152·78in. for the rack, having 120 teeth. The pitch of the teeth is 4in. and width of face is 7in.

Each motor is equipped with a full-torque solenoid brake, the two brakes on each tower being so connected that in addition to operating with their respective motors, either one can be operated independently from the operating house, as an emergency brake, while the corresponding motor is running idle. The motors are synchronised, and are operated by a magnetic control in the operating house. Limit switches cut off the power and set the brakes as the moving span nears the end of its travel in either direction. Its final movement is then controlled by a separate switch that provides only a low power. The power equipment is designed to raise the bridge 50ft. in 105 seconds. Current is delivered by a cable laid in the bed of the river.

ELECTRIC CONTROL OF LIFT BRIDGES.

In the Des Plaines River bridge above described and in the Missouri River bridge of the Missouri, Kansas and Texas Railroad, synchronising equipment is used to maintain the lift span automatically level during its movements up and down. In other bridges a manually operated levelling device is employed. Where electric power is used it is general practice to provide two motors on each tower, one being operated normally and the other providing for reserve or emergency. But in these two bridges a special feature is the synchronising of the motors. On each tower, both the primary motor and the secondary or synchronising motor are connected to the main train of gearing, as described, the latter motor being driven against its normal phase rotation. The mechanisms on the two towers are connected by a three-phase cable which connects the slip rings of the two synchronising motors. If one of the primary or lifting motors should tend to slow down its speed, owing to unequal loading, there is an immediate phase shift in the rotors of the secondary or synchronising motors, and a rotor current flows from the one tending to run at the higher speed to produce torque in the other tending to run at lower speed. This prevents any change in the average speed of the two primary motors. In case of emergency, such as failure of a primary motor, its corresponding secondary motor can be corrected immediately as a primary motor, thus serving the same purpose as the usual duplicate or reserve motor.

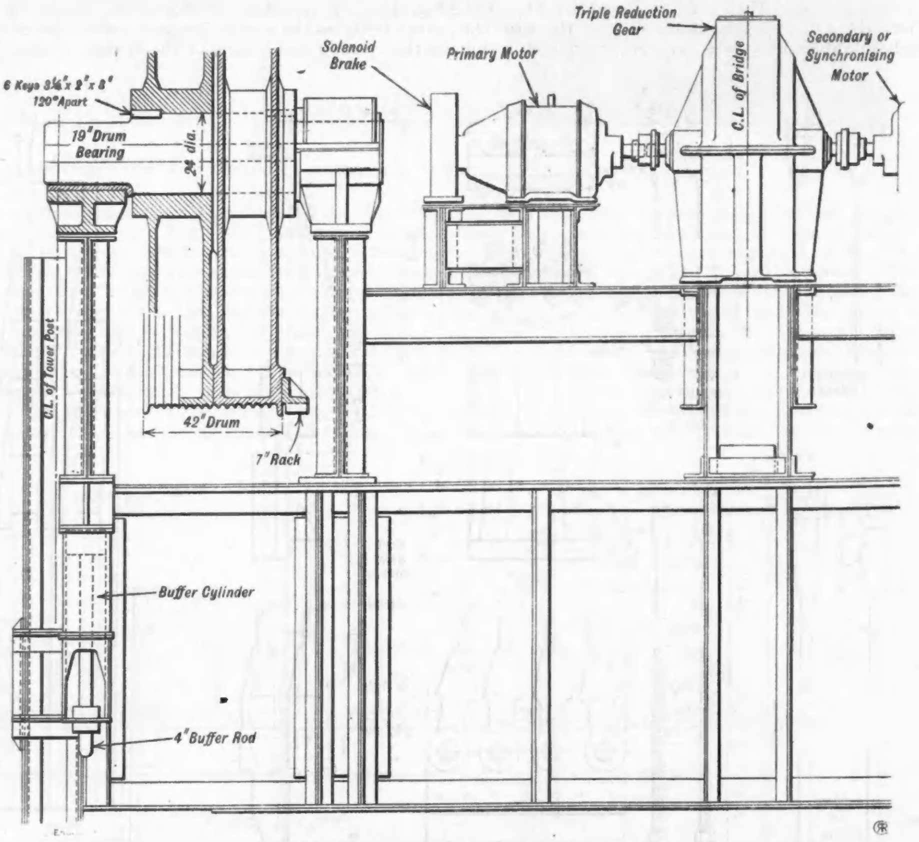

FIG. 15—ARRANGEMENT OF HOISTING MACHINERY—DES PLAINES RIVER BRIDGE

BRIDGE LOCKS AND SIGNALS.

At the end of its travel, either up or down, the span is brought to rest gently by means of air buffers. In rising, the bridge chords engage the plungers of four inverted cylinders carried by the head frames of the towers. In lowering, as shown in Fig. 15, the plungers of similar cylinders, 12in. diameter and 24in. stroke, attached to the bottoms of the end floor beams, engage striking plates on the tops of the masonry piers. The guide wheel arrangement, which steadies the span when moving, has been described already.

Centre locks of the bolt or plunger type on the ends of the lift span engage attachments on the end floor beams of the tower spans, thus insuring that the bridge is at the proper alignment and level. In the Des Plaines River bridge above described, the bottom chords of the lift span are locked with those of the tower spans when the bridge is closed. At the fixed end a T-headed lug at the end of each chord of the lift span engages a T-shaped socket on the chord of the adjacent tower span. At the expansion end, the lug is a straight bar or torque engaging a straight slot, and is therefore free to slide longitudinally in the slot.

The track and guard rails on the lift span extend beyond the ends of the floor, bridging the gaps between the lift span and fixed spans. Their ends are tapered, and as the bridge lowers, they seat against the sides of the tapered ends of the fixed rails, which are secured in steel castings. Inclined guides bring the moving rails into proper position in the castings, and these rails are then automatically locked in place.

Railway signals on the bridge approaches are interlocked with the bridge operating mechanism, and are repeated in the machinery house by indicators. In this house, also, other devices indicate the position of the bridge when moving and the positions of all locking mechanisms. Miniature lamp signals indicate when all the four corners of the span are fully seated on their bearings and the bridge is in position to carry trains. Before the span can be raised, the operator must set the signals against trains on both approaches. Until he does so he cannot release the end locks which hold the span in place. He must then energise the bridge interlock relay, thus permitting power to be applied to the bridge control mechanism. The same mechanism also prevents any change being made in the railway signals.

Tracks on Lift Bridges.

On the railway bridges, different arrangements of tracks are used. In almost all cases the floor is of open construction, with the rails seated on base plates on ties—or sleepers—resting on the longitudinal girders of the floor framing. On the Boonville Bridge, the flat-bottom rails are secured in heavy cast steel chairs by means of bolted clips, on the system of the latest standard track of the German railways. As a rule, also, there is a guard rail a few inches inside each running rail, and a timber guard along the ends of the ties to hold them in position.

Some of the bridges are on single-track lines, and others on double-track lines. The Hackensack River bridge of the Delaware, Lackawanna and Western Railroad has three lines of rails. For its four-track main line crossing the Calumet River, near Chicago, the New York Central Railroad has a four-track lift bridge. But the four-track line of the Pennsylvania Railroad over the same river has twin double-track bridges, side by side. This railway also has a similar arrangement of twin double-track bridges on its four-track line crossing the Chicago River, this arrangement facilitating traffic during the construction of the bridges.

The Missouri River bridge of the Missouri, Kansas and Texas Railroad has a single track, but to provide for double-tracking of the line the bridge is made wide enough for gauntleting a second track. The rails will be 9in. apart, the centre line of each track being offset 4½in. from the centre of the bridge. The rails for each track, therefore, serve as guard rails for the other track. This arrangement avoids the greater expense for a double-track bridge, with its larger foundations, piers and superstructure, while it also avoids the complications of two sets of points and crossings and interlocking signals to connect the double-track line with a single track across the bridge.

This gauntlet arrangement of tracks is employed also on the Des Plaines River bridge of the Chicago, Rock Island and Pacific Railway, although this bridge carries a double-track main line. But at Joliet the railway goods yards and running sheds are on the opposite side of the river from the city, so that there are frequent shunting movements across the bridge in connection with local coal yards, goods stations, and factories. With the gauntleted tracks, the lines of rails used for such shunting service are independent of the main track rails, thus avoiding the expense of installing, operating, and maintaining sets of points and crossings, with the added complications of signals and interlocking plants.

Highway lift bridges have usually floors of light construction, in order to reduce the weight. But on the two Hudson River bridges mentioned a heavy concrete slab floor is provided, with correspondingly heavy steel floor framing, as the road carries a dense traffic and the bridges are designed to carry 20-ton motor trucks.

Designers of Lift Bridges.

Modern application and development of the vertical-lift type of drawbridge or movable bridge began in 1894 with the Halsted-street bridge over the Chicago River. This bridge was designed by Mr. J. A. L. Waddell, consulting engineer, and the design was adopted in the face of strong opposition by engineers and local authorities, who were positive that such a bridge would not work. Since then, however, numerous bridges have been built to Mr. Waddell's designs, both by himself and by other engineers associated with or in partnership with him. His system, which is covered by his patent and those of different engineers, is based on the triple system of cables, already described, in which machinery on the lift span operates two separate groups of cables for hauling the bridge up and down, while the span is suspended by a third group of cables attached to counterweights.

Rocking lever systems to operate the span and so eliminate all cables were introduced about 1912 by two engineers, acting independently—Mr. Charles L. Strobel and Mr. Joseph B. Strauss. Only a few bridges of this type have been built. In both designs the operation is by means of power-driven pinions at the four corners of the bridge and engaging vertical racks on the posts of the towers.

A more important development was made about 1926, when the engineers of the Chicago, Rock Island and Pacific Railway, in designing the White River bridge, determined to eliminate the two sets of operating cables and to utilise the counterweight cables for operation as well as suspension of the span. This was done by placing the power machinery on the tops of the towers and gearing it to the cable sheaves. This direct-lift method was opposed as impracticable by some bridge builders and electrical engineers. However, the railway's engineering department was sure of its ground and had the courage of its convictions. The plan was adhered to, therefore, and the bridge was built as designed, under the direction of Mr. W. H. Petersen, chief engineer, and Mr. I. L. Simmons, bridge engineer.

As this first direct-lift bridge was entirely successful, from both the practical and economic points of view, the system has been followed in several later bridges. It has advantages in simplicity and reduced cost, and in eliminating the complications arising from three separate groups of cables, and relieving the lift span from the weight of operating machinery. This direct-lift system is not covered by patents. To the engineering department of the same railway is due the further step of eliminating the complications of cable equaliser connections by the use of pre-stressed cables cut to exact length, as already described.

Economic Mine Ventilation.

By Chief Engineer M. SCHAEFER, Bochum, Germany.

Fans for the ventilation of mines belong to the class of mine-working machinery required to be in continuous operation. The constant presence of numerous persons underground and the necessity of removing firedamp or other dangerous gases, compel us to keep the "lungs of the mine" in perpetual motion. Consequently, fans frequently form part of the mine equipment involving heavy working costs, and for this reason many mining officials aim at obtaining the highest possible economy in mine ventilation. The ways and means adopted for achieving this aim are in the main known, and it is therefore proposed to touch upon them briefly in the following article.

Above all things, the area of the mine passages has a predominating influence on all points bearing on mine ventilation. The power consumption of the ventilating plant and the working costs depend primarily upon this factor. This is all the more evident when the fact is recalled that the depression increases or decreases as the square of the variation of the mine area, the capacity of the fan being constant, with the result that the power consumption and working costs vary practically in the same ratio. By increasing the mine area twofold, the working costs would be reduced to roughly one-quarter. Hence, every effort should be made to make the mine area as large as possible. By compounding several shafts to a common up-cast shaft, it has repeatedly been possible to augment the mine area very considerably. The area may frequently be increased to a smaller extent by reducing the resistances in the shaft; for instance, by substituting grids for the timber platforms, this applying chiefly to narrow shafts.

The action of the fan is a factor of hardly less importance in its bearing on the working costs. As long as the capacity and power consumption of the fans were within narrow limits, low efficiencies could be put up with. However, when the air volumes to be moved increased at a constant rate, and the power consumption rose in a considerable measure, low efficiencies involved considerable losses in working costs. By carefully designing all fan details in accordance with the results of exhaustive research, it was possible gradually to increase the efficiency very considerably. At the present day efficiencies of 75 to 80 per cent. and even more are of frequent occurrence.

The correct selection of the driving unit is likewise of great influence in economic respects, the selection always depending upon the special features of individual cases. In mines where steam power is available, the main point to be decided is whether preference is to be given to steam or electrical drive. By using steam as a driving medium, the working costs may in many cases be reduced very appreciably, notably by suitably utilising the exhaust steam of the driving engine, for instance, in mixed-pressure turbines, for generating the supply of electric current or compressed air. A saving in working costs is particularly noticeable when the exhaust steam is used for heating the feed water for the boilers. This will at once be evident when it is taken into account that in such a case an almost completely closed circulation of the heat of the steam is obtained, from which only that quantity is extracted which the machine converts into power, and which gets lost in the piping by radiation and leakage. By far the major part of the heat is, however, returned to the boilers with the feed water.

Electrical drive should be chiefly selected only for shafts used purely for ventilating purposes, steam power being rarely available at shafts of this description.

Amongst the variety of measures adopted for obtaining efficient working conditions, mention may here be made of the use of cascade motors for plants of an extensive nature.

The position of the fan relative to the shaft, to the boiler plant, to the point of consumption of the waste steam, &c., should likewise be carefully considered if economic drawbacks are to be avoided. The proportioning and manner of laying out the intake conduit on the surface and connecting it with the shaft and fan can effect its total resistance very considerably, and even influence the efficiency of the fan.

An advantageous arrangement of a single and double-inlet fan, and a favourable airway designed to give the most satisfactory results, are shown in Figs. 1 and 2, the arrangement being derived from actual practice.

Efficient attendance and care of the plant will at all times be worth the cost. As a matter of course, the interior of the fan should be kept free from dirt, the volute casing cleared of water, the most suitable lubricating oils used, overhauling done in good time, and the efficiency tested at regular intervals.

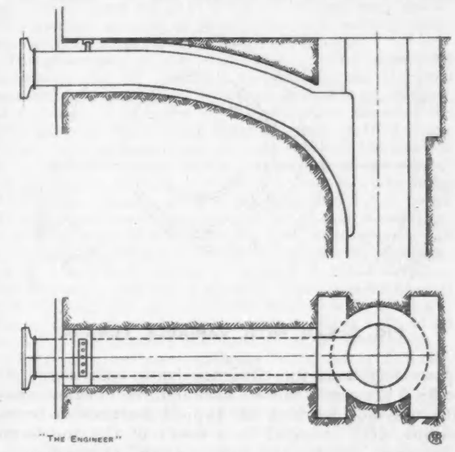

Fig. 1—Arrangement of Single Inlet Fan

Fan Design.

The aforesaid ways and means will, however, only suffice for obtaining or maintaining the highest economy, provided a further condition is fulfilled at the same time—the fan must at all times be suitable for the mine area. Experience has proved, however, that this requirement is in many cases not met, and the explanation is not difficult to account for. Owing to the advance in the mine workings, the airways are liable to constant variations, this involving variation of their resistance or of the equivalent mine orifice. On the other hand, the passages of a fan designed according to current practice remain unaltered. As a consequence, disagreement in a more or less marked degree is bound to follow on the necessary constant agreement; if, indeed, agreement had existed at the outset.

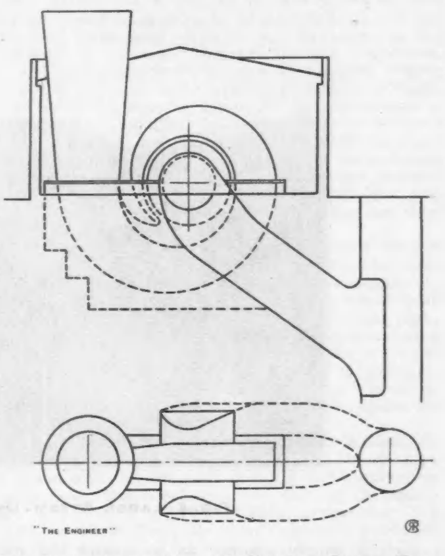

Fig. 2—Arrangement of Double Inlet Fan

The results are known. If the mine area increases, the period is soon reached when the air capacity of the fan no longer increases at the same ratio as the area increases. A gradual falling off in the manometric effect and efficiency is discernible. If the mine area decreases, a reduction of the proportionality is revealed, and in this case the efficiency is constantly lowered. Ultimately a pumping action of the fan is set up, causing shocks in the casing and chimney, or vibrations of the shaft which may become so serious that the reliability in working is endangered. In some cases the fan may emit a humming noise.

Among the numerous tests available, it is proposed to give two examples which clearly show the drawbacks of faulty agreement.

A double-inlet electrically driven suction fan, having a capacity of 350,000 cubic feet per minute, which from the outset ran at full speed, revealed a very strong pumping action when first put into operation. It could not be used for continuous service until over 150,000 cubic feet per minute of fresh air had been admitted into the fan intake conduit. This caused the working costs to rise by roughly 30,000 gold marks per year. Subsequent examination revealed the fact that, owing to unforeseen circumstances, the mine area at the time was very much smaller than had been estimated in advance by the mine officials, and on which the design of the fan had been based. It is proposed to refer to this case later.

A single-inlet suction fan, having a capacity of 247,000 cubic feet per minute, designed for a mine area of 23·7 square feet was tested at a capacity of 201,500 cubic feet per minute, the area being 36·4 square feet, and the efficiency being ascertained to be 58·5 per cent. Hence, although the normal capacity was not reached, all typical features of overloading were revealed as a result of the too large mine area. Neither the volume of air nor the depression were in the correct ratio to the revolutions or to the increase in the size of the mine area, and the power consumption was too high. The volume of air should have been about 12 per cent. higher, and the depression 24 per cent. higher, the efficiency should have been not less than 73 per cent. The extra consumption of current was calculated to be roughly 360,000 kW per year. If the fan had been working at its full capacity, the current consumption would have been almost twice the amount.

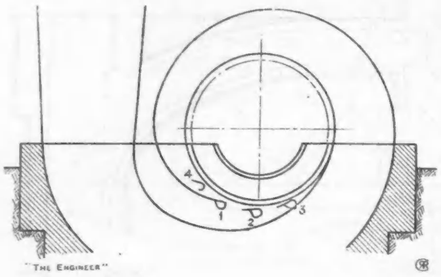

FIG. 3—FAN WITH VARIABLE TONGUE

CONTROLLED FAN PASSAGES.

A satisfactory elimination of such losses in working costs, frequently incurred for years, was first made possible by the introduction of a process which provides the means for influencing the fan passages in such a simple manner as to ensure the most favourable area of the passages for any capacity of the fan.

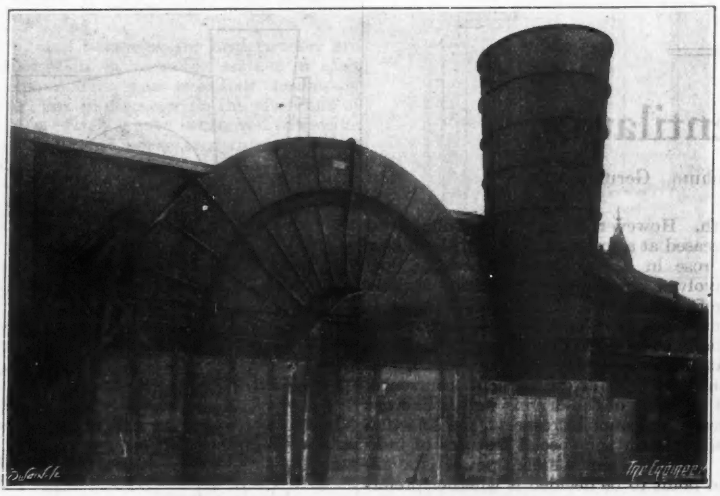

FIG. 4—LARGE STEAM-DRIVEN MINE VENTILATING FAN

The "area of the passages" of the fan is a conception similar to the "equivalent mine orifice." Hence, it would be more correct to say "equivalent area of the passages." Both represent a measure of the resistance to the passage of the air, on the one hand, through the fan passages, and, on the other hand, through the mine drifts. In the same manner as the lowest resistance denotes the greatest and economically most favourable mine area in the latter case, it signifies the greatest passage area and the best efficiency in the former case.

It will not be necessary to state the reason why the widest passages cannot always be considered identical with the greatest passage area. The proportioning of the passages results primarily from the constructional principles in each individual case, and remarkable differences may be encountered in various fan designs.

Now, whereas the size of the passages of the fan of a mine having a constant equivalent orifice remains constant from the lowest to the highest fan capacity, and *vice versâ*, it requires to be correspondingly rectified when the mine area is varied. In the process under consideration this is accomplished by shifting the position of the tongue in the fan casing.

It is still current practice to adhere strictly in other fan systems to the position once selected of the tongue of the volute. In a few fan types of older date the practice of shifting the tongue was adopted, but this was done for other purposes and does not in any way touch upon the principle of the process under consideration.

Fig. 3 represents various positions of the tongue by way of example. Let position 1 be the normal position, corresponding to a mine area of 32 square feet. As long as the latter remains unchanged, the position of the tongue is not altered for either lower or higher capacities of the fan. On the other hand, if the mine area is reduced, say, to 27 square feet, then the tongue is shifted to position 2, which would be fixed for this area. If the area is reduced still more, the tongue finally reaches the position 3, corresponding to an area of 21·5 square feet, &c. If the area is increased beyond 32 square feet, the tongue is moved, say, into the position 4, corresponding to an area of 38 square feet, and so forth.

By shifting the tongue in this manner, the possibility is given of influencing the passages to such a favourable degree that their total resistance is reduced to a minimum in each individual case, and the passages increased to a maximum. It is possible to attain an efficiency for each position of the tongue not lower than that of another fan specially designed for the corresponding mine area.

The successful results of the adjustment will be recognised from the following examples :—

(1) In the case of the previously mentioned double-inlet suction fan, with a capacity of 350,000 cubic feet per minute, the occasion presented itself of subsequently fitting the tongue adjusting device, with the result that the pumping action of the fan stopped immediately and the admission of outside air into the intake conduit was no longer needed. The fan then worked satisfactorily at its maximum speed and at about one-third of its maximum capacity, the hitherto incurred extra working costs being saved.

(2) A single-inlet electrically driven suction fan with a normal capacity of 212,000 cubic feet per minute was to be connected with an air shaft used till then as a downcast shaft. After a corresponding advance of the mine workings, a mine area of 32·3 square feet was selected for this volume of air. The initial area was difficult to foresee, and it was estimated, so far as this was possible, to be about 16·15 square feet. As will be evident from the following, it was at first still smaller. It was decided to build the fan for a normal mine area of 32·3 square feet, but to make it adjustable down to 16·15 square feet. The capacity was to be 106,000 cubic feet per minute for an area of 16·15 square feet and a speed of 245 r.p.m.

The fan was adjusted during erection for a mine area of 16·15 square feet, the following results being obtained at the test :—

R.p.m.	249
Cubic feet per minute	95,000
Depression	6·7in.
Input to motor	104 kW
or	141·5 H.P.
Air power of fan	101 H.P.
H.P. at the fan shaft at an efficiency of the motor of 92 per cent. and of the belt pull of 95 per cent.	123·5 H.P.
Equivalent mine orifice	14 sq. feet
Total efficiency	71·5 per cent.
Approximate efficiency of fan	82 per cent.

(3) A single-inlet suction fan of older date, originally provided for a capacity of 495,000 cubic feet at a mine area of 53·8 square feet, was to be so reconstructed that it constantly moved the greatest possible air volume at mine areas varying from 43·1 to 64·6 square feet and a constant speed of 225 r.p.m., and so that the flexibly coupled three-phase motor of 1500 horse-power was at all times fully loaded.

The following results were agreed to :—

Mine area, sq. feet.	R.p.m.	Capacity, cubic feet per min.	Depression, inches.
43·1	225	434,000	14·95
53·8	225	509,000	13·1
64·7	225	565,000	11·2

Provision was to be made to curtail the vanes of the fan wheel for dealing with areas greater than 43·1 square feet, so that the air capacity was correspondingly reduced and the motor not overloaded.

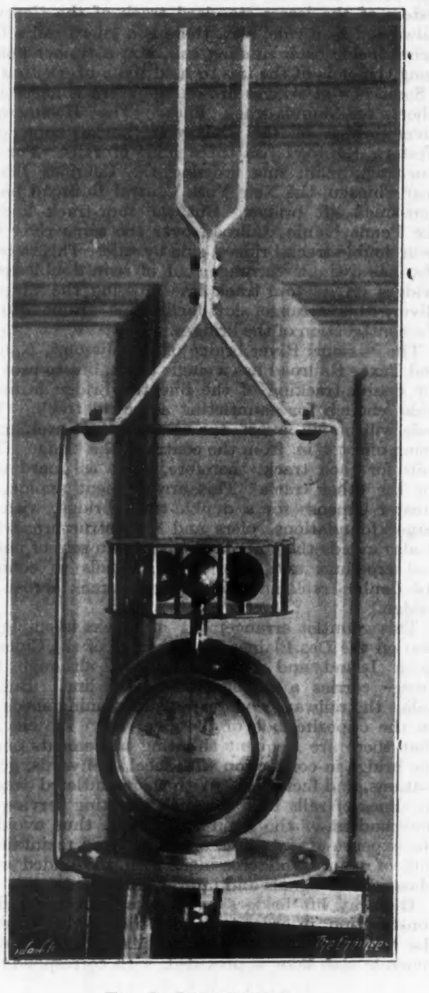

FIG. 5—ANEMOMETER

After reconstruction the fan was adjusted to 43·1 square feet, a larger area not being expected to be required for the time being. The results of the test carried out with the full length of the vanes were as follows :—

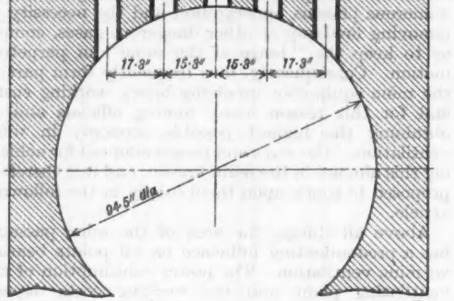

FIG. 6—MEASUREMENT POINTS

R.p.m.	227·25
Cubic feet per minute	431,000
Depression	16·05in.
Input to motor	1082 kW
or	1470 H.P.
Air power of fan	1105 H.P.
H.P. at fan shaft at an efficiency of the motor of 93 per cent.	1367 H.P.
Equivalent mine orifice	41·25 sq. feet
Total efficiency	75·2 per cent.
Efficiency of fan	80·86 per cent.

(4) An electrically driven fan of 282,000 cubic feet capacity was to be installed for increasing the ventilation of a main mine plant. As a result of an exhaustive estimation of profits, however, a fan*

---

* The fan was supplied by Westfalia-Dinnendahl-Gröppel A.-G., of Bochum, Germany.

directly coupled to a single-cylinder superheated steam engine† was installed. The exhaust steam of the engine is used for preheating the boiler feed water, very economical working being thereby achieved in respect of heat expenditure.

In order to increase the mine area, two shafts were to be compounded to form one upcast shaft, and corresponding measures were to be taken underground. It was expected gradually to attain a mine area of about 34·4 square feet in this manner.

At first it appeared impossible to obtain an area slightly exceeding 16·2 square feet. Hence, the fan was to be made adjustable to a mine area of about 16·2 to 34·4 square feet. The best arrangement was obtained with a double-inlet fan. According to agreement, the fan was to run at a maximum speed of 135 r.p.m. Fig. 4 represents the fan.

In the course of erection the fan was adjusted to a mine area of about 16·2 square feet and tested, the following results being obtained :—

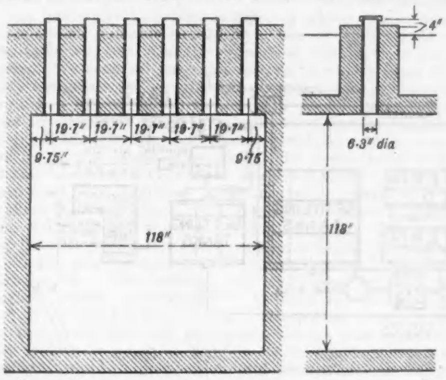

FIG. 7—MEASUREMENT POINTS

R.p.m.	129·2
Cubic feet per minute	295,000
Depression	10·08in.
Air power of fan	475 H.P.
Indicated power of steam engine	664 H.P.
Total efficiency of plant	71·5 per cent.
Equivalent mine orifice	35·64 sq. feet

The builders of the steam engine guaranteed a mechanical efficiency of 92 per cent. at 650 indicated horse-power. Actually, it seems to have been rather more. Taking it as 93 per cent., the efficiency of the fan worked out at roughly 76·88 per cent.

After the mine area had by calculation been ascertained to be 35·64 square feet by this test, the fan was adjusted to 34·4 square feet, and about four months later a new test was carried out, the results being as follows :—

R.p.m.	130·7
Cubic feet per minute	283,000
Depression	10·71in.
Air power of fan	484 H.P.
Indicated power of steam engine	624 H.P.
Total efficiency of plant	77·6 per cent.
Equivalent mine orifice	33·1 sq. feet

Taking an efficiency of 92·5 per cent. of the engine for the lower rate of indicated horse-power, the fan efficiency works out at 83·9 per cent., this representing an improvement on the previous efficiency of 9·13 per cent. brought about by the adjustment. The improvement on the depression is also worthy of note, this being attributed in a relatively small measure to the slightly higher speed.

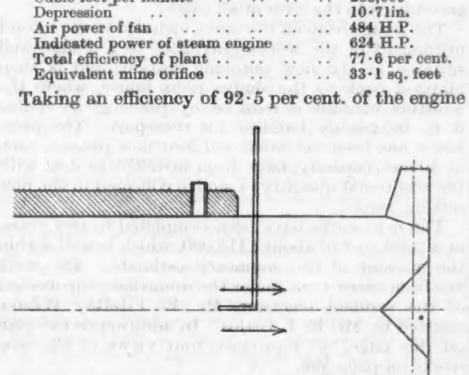

FIG. 8—POSITION OF PITOT TUBE

These tests were carried out when the mine was working at its full capacity. In a third test, instituted after the mine had been in operation about four months, and made when the mine was not working, the total efficiency of the plant was 77·7 per cent., the load being practically of equal magnitude.

It is a regrettable fact that, owing to the working conditions, the mine officials can seldom allow more than one test to be made under the working conditions prevailing at the moment. It goes without saying that a series of tests would be of general interest. Nevertheless, the above test results are sufficient proof of the advantageous behaviour of the adjustable fan under the working conditions in each individual case.

A few words may be added regarding the basis on which the tests were carried out.

BASIS OF THE TESTS.

All tests were made in accordance with the rules framed by the Verein deutscher Ingenieure for testing fans. The air volumes were measured by anemometers provided with cups fixed on a cross, these instruments being specially adapted for high velocities. These instruments are timed to run for three minutes, this period being automatically controlled by clockwork. The clockwork is enclosed in a casing of spherical form in order to eliminate faulty readings which are liable to occur in flattened clock cases. The cross with the cups works between two discs provided for guiding the air.

The instrument shown in Fig. 5 allows the readings to be taken correctly. The instruments were specially calibrated before and after each test by the Berggewerksschaftskasse, of Bochum.

Whilst the test (4) was being carried out, measurements were occasionally also taken by using a Prandtl tube. The results were in agreement with those obtained by the anemometer.

Figs. 6 and 7 show the points of measurement of the air for tests (2) and (4). The anemometers were secured in frames and moved evenly up and down by means of rods at each measuring point for about four to five minutes in each case. The mean velocity was thus ascertained on full measuring lines and not at single points of the area to be measured.

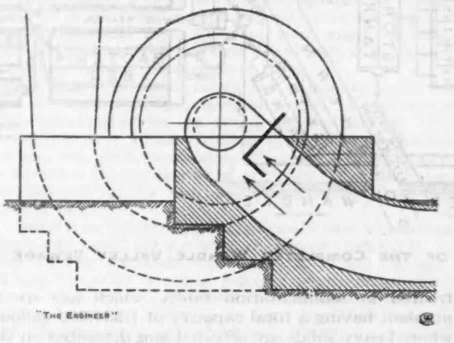

FIG. 9—POSITION OF PITOT TUBE

When anemometers are used with a frame as described they must be calibrated together with the frame.

The depression was ascertained close to the fan during the total duration of the tests at regular intervals by means of Pitot tubes, arranged as shown in Figs. 8 and 9, the reading representing the *total pressure*, and thus the static pressure less the velocity pressure, the mean pressure being inserted in the formula for calculating the air power. This simple method of measurement is, as a rule, preferable to the more complicated method of independently ascertaining the static pressure and velocity pressure.

The input of current to the motors was measured by calibrated current meters. The springs of the indicators were newly calibrated for every test, while the planimeters were tested as to their correct reading.

---

† The engine was supplied by Gebr. Stork and Co., of Hengelo, Holland.

Electricity Supply, 1931–32.

THE Return of Engineering and Financial Statistics relating to Authorised Electricity Undertakings in Great Britain for the year ending March 31st, 1932, or May 15th, 1932, for public authority undertakings, and December 31st, 1931, for company undertakings has been issued by the Electricity Commissioners. Exclusive of new stations and extensions to existing stations which had been sanctioned but not brought to completion within the period covered by the return, the generating stations belonging to authorised undertakers in Great Britain, of which particulars are given, numbered 464. The total capacity of plant installed in the stations at the end of 1931–32 was 7,194,571 kW. Public authorities had 249 stations and companies 215 stations, with aggregate capacities of 4,665,160 and 2,529,411 kilowatts respectively.

The net addition to plant during the year amounted to 248,766 kW, as compared with 345,580 kW during the previous year. Of the total, 100,000 kW was accounted for by the coming into operation of the new Clarence Dock station of the Liverpool Corporation, a selected station for the purpose of the North-West England and North Wales Electricity Scheme. The 79 largest stations (20·9 per cent. of the total), each having an installed capacity of 25,000 kW or over, contained 5,612,667 kW of plant, or 78 per cent. of the total plant installed. Of the remaining 367 stations, 184 had an installed capacity of less than 1000 kW each.

As compared with the position at the end of 1930–31, there was an increase of 264,530 kW in the amount of steam turbine plant; a decrease of 16,135 kW in the amount of reciprocating steam plant; and an increase of 3026 kW of oil engine plant. A.C. plant represented 6,931,938 kW, or 96·35 per cent. of the total, and D.C. plant 262,633, or 3·6 per cent. During the year there was an increase of 263,798 kW in the amount of A.C. plant, and a decrease of 15,032 kW in the amount of D.C. plant. As much as 6,790,526 kW, or 94·38 per cent. of all the generating plant installed by authorised undertakers in Great Britain, consisted of steam turbo-alternators. There were 1197 A.C. units and 873 D.C. units with 161 and 125 kW rated capacities respectively. The D.C. plant comprised units having rated capacities ranging from 4 kW to 6000 kW, and the A.C. plant units from 10 kW to 50,000 kW; 250 A.C. units of 10,000 kW or over were installed in the generating stations of authorised undertakers, the aggregate capacity of the units in question amounting to 4,280,500 kW, and representing over 59 per cent. of the total capacity installed by all authorised undertakers.

One hundred and ninety-two stations generated A.C. only; 92 stations produced both A.C. and D.C.; and 180 stations D.C. only. Of the 284 stations at which A.C. was generated, in 196 cases a generation pressure of 6000 volts and upwards was adopted, either wholly or in part, a large majority of these cases representing three-phase, 50-cycle generation at 6600 volts. At 41 stations generation was carried out either wholly or in part at pressures of 10,000 volts or over. In 33 cases A.C. generation was carried out at voltages below 650, and in 60 other cases at voltages ranging between 1000 and 3000 volts. In the majority of cases the D.C. pressures ranged from 400 to 500 volts, but as many as 69 stations contained D.C. plant generating at pressures not exceeding 250 volts.

The generation of A.C. was carried out by authorised undertakers at 11 different frequencies, the accepted standard frequency of 50 cycles per second being the predominating one in vogue at 274 generating stations, the other principal frequencies being 25 cycles at 15 stations and 40 cycles at 11 stations. As compared with the position at the end of the year 1930–31, there was an increase of 437,380 kW in the amount of 50-cycle plant and a decrease of 173,582 kW in the amount of non-standard A.C. plant. The aggregate capacity of the 50-cycle plant installed at the end of 1931–32 was 5,918,281 kW, as compared with a total of 1,013,657 kW for all other frequencies, representing 85·4 and 14·6 per cent. for all A.C. plant installed. The predominating non-standard frequencies of 25 and 40 cycles together accounted for 942,550 kW, or 93 per cent. of the non-standard plant. Over 81 per cent. of all the A.C. plant installed was three-phase, 50-cycle plant.

The total evaporative capacity from and at 212 deg. Fah. of the boiler plant installed in all generating stations dealt with in the return was 81,683,651 lb. per hour, the figure for public supply authorities being 56,042,308 lb. per hour, and that for company stations 25,641,343 lb. per hour. The boiler plant was made up of 2405 units, having 166 differently rated evaporative capacities, ranging from 1500 lb. to 220,000 lb. per hour, and 48 different working pressures, ranging from 100 lb. to 475 lb. per square inch. The steam-raising plant in the generating station of the Bradford Corporation works at 1100 lb. per square inch.

Over 76 per cent. of the aggregate capacity in 1931–32 was accounted for by boilers having an hourly evaporative capacity of 30,000 lb. and upwards, as compared with 75 per cent. in the previous year and less than 30 per cent. in 1920–21. Boilers having a working pressure of less than 200 lb. per square inch represented under 16 per cent. of the aggregate boiler capacity in 1931–32, as compared with over 56 per cent. in 1920–21.

Excluding the Bournemouth Corporation, where supplies were given for public purposes only, the distribution system of the other 659 undertakings were A.C. in 269 cases, A.C. and D.C. in 286 cases, and D.C. only in 104 cases. While A.C. generation was carried out by authorised undertakers at 11 different frequencies, supplies of 12 different frequencies were distributed. In addition, a bulk supply at 30 cycles was obtained from a non-statutory source. At the end of 1931–32 supplies at two or more frequencies were being given by 23 undertakings, but in a number of these cases steps were being taken by the undertakers to eliminate the non-standard frequencies. Low and medium-pressure supplies at voltages, ranging from 100 to 480, were being given at 37 different voltages in the case of A.C. supplies and at 25 different voltages in the case of D.C. supplies, the total number of declared voltages within the range in question for both classes of supply taken collectively being 46, these figures including associated pairs of voltages. There were nine declared pressures exceeding 100 volts, but less than 200 volts, and 21 declared pressures exceeding 200 volts but less than 400 volts.

During 1931–32 public authorities generated 6905·6 million units and companies 4627·1 million units, compared with 6544·7 million and 4402·8 million respectively during 1930–31. The number of units generated in 1931–32 showed an increase of over 585 million, or 5·3 per cent., on the figures for 1930–31. The sales to consumers during the year showed an increase of 427 million units, or 4·7 per cent. on the figures for 1930–31. The number of consumers connected at the end of the year showed an increase of upwards of 634,000, or 15·8 per cent., on the figures for the previous year.

The requirements of the electricity supply industry in 1931–32 involved the consumption of over 8,736,000 tons of coal and coke, besides comparatively minor quantities of other fuel. Pulverised fuel was used by 20 undertakers to the extent of 1,055,318 tons, representing 12·1 per cent. of the total tonnage of coal and coke consumed during the year.

The progressive improvements in steam power station equipment and practice since 1920–21 have resulted in a reduction of the average fuel consumption per unit generated from 3·42 lb. in that year to 1·78 lb. in 1931–32. From the figures of the ratio of outputs per ton of fuel consumed given in the present and preceding returns, the conclusion may be drawn that technical developments have resulted in an all-round increase of 92 per cent. in the amount of electricity now obtainable per ton of fuel consumed at generating stations of authorised undertakers as a whole, as compared with the position in 1920–21.

THE Import Duties Advisory Committee gives notice of applications for an increase in the import duty on: Tools (except forks, shovels, spades, scythes, sickles, agricultural implements, screw taps and dies with ground threads and blow lamps for liquid fuel of pressure type), including domestic tools, but not including machine tools other than the separable cutting, drilling, screwing, milling, forming, and holding parts used in machinery or in machine tools, and parts thereof.

Wandle Valley Sewage Disposal.

The Wandle Valley Joint Sewerage Board was formed in 1916 in order to deal with the sewage from the constituent urban districts, which include Mitcham, Merton, Morden, Beddington, and Wallington. For many years sewage had been purified at the existing works near Byegrove-road, by treatment in sedimentation tanks, followed by contact beds, but at the time when the Board was formed these works had become totally inadequate and unsuitable for the efficient purification of the sewage from the population of the joint district.

The Board having decided to proceed with a comprehensive scheme of purification by more modern methods, including the provision of percolating filters to replace the old contact beds, the construction of the first instalment of this scheme was begun in 1922 and completed in 1925 at a cost of about £231,000. During the construction of these works the population had rapidly increased from 70,000 in 1922 to about 100,000 in 1925, and by 1929 had reached 115,000, the dry-weather flow of sewage being 4 million gallons per day, or about 25 per cent. in excess of the capacity of the first instalment of the works as designed. The principal reason for the exceptionally rapid increase of population was the development of building estates within the Board's area, particularly the London County Council estate at Morden, where houses had been erected to accommodate a population of about 25,000.

The Board was therefore compelled to provide for this rapid growth of the population, and in order to deal with the additional flow of sewage, it was decided in 1928 to proceed with the construction of the second instalment of the sewage disposal works. The Board therefore instructed Messrs. Willcox and Raikes, of Westminster and Birmingham, the engineers to the original scheme, to prepare the necessary detailed plans and estimates for submission to the Ministry of Health. These plans were duly approved by the Ministry and the loans sanctioned in April, 1931. The tender of William Moss and Sons, Ltd., of Loughborough, was eventually accepted for the whole of the structural work which was begun on November 9th, 1931.

The extensions have just been completed, and provide for treating an additional quantity of sewage amounting to 2 million gallons per day. This quantity necessitated the provision of new works of about two-thirds the capacity of the first instalment. The whole of the sewage is brought to the works by high-level and low-level systems of sewers, the high-level sewage being passed through screens with mechanical raking gear ; but as the low-level sewage is pumped by special " Stereophagus " pumps which break up all large solids, it is unncessary to install screens for this portion of the sewage flow. The sewage from the low-level system of sewers, together with about half of that from the high-level system, is treated on the first instalment of the works, and the remainder of the high-level sewage gravitates to a pump well at the new pumping station where pumping plant has been installed to raise the whole of the sewage for treatment by the second instalment of the works. It has been necessary to construct the tanks and bacteria beds included in the extensions above ground in the same manner as in the case of the first instalment, in order to provide sufficient fall to enable the final effluent to drain by gravitation to the main effluent conduit which discharges into the river Wandle at Western Pool.

The works included in the second instalment comprise the provision of screening plant, sewage and sludge pumping station, sedimentation tanks, bacteria beds and humus tanks, as well as storm water tanks and extensions of the arrangements and plant for sludge pressing. The plant installed at the pumping station includes six centrifugal pumps, three of which are required for raising crude sewage to the sedimentation tanks, and three for lifting storm water to the storm water tanks. There are also two vertical-spindle centrifugal pumps for pumping sludge back to the sludge-pressing house. The whole of the pumping plant is electrically driven, and automatically controlled by means of float switches, in order to ensure that the number of pumps in operation at any time will be in proper relation to the flow of sewage without the necessity of constant supervision by an attendent. Two Venturi meters and recorders are installed at the pumping station for measuring the quantity of sewage and storm water discharged by each set of pumps.

To meet the requirements of the Ministry of Health the sewage up to three times the dry-weather flow is treated in sedimentation tanks, which are six in number, having a total capacity of 1,334,000 gallons, where heavy solids are arrested and deposited on the floors in the form of sludge, which is removed at intervals and pumped back to the press house for treatment. After passing through these tanks the sewage still contains a percentage of light solids in suspension, together with colloidal matter, and in order to reduce the amount of this material before passing the effluent on to the filters, it is given a further period of settlement in six upward flow straining tanks, each measuring 18ft. by 18ft. by 17ft. deep, having a total capacity of 134,000 gallons. These tanks are of the Dortmund type with pyramidal bottoms. The inlet to each of them is so constructed that the sewage enters near the bottom. The solids settle in the lower part of each tank, while the liquid portion rises slowly to the surface, and is discharged over weirs into collecting channels.

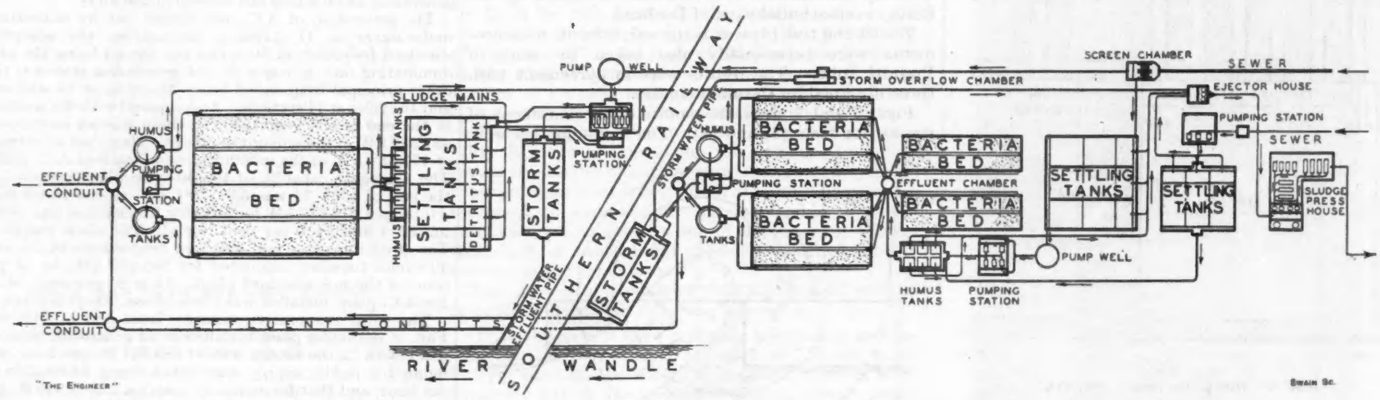
From these channels the tank effluent is discharged by gravitation to two rectangular bacteria beds, where the solids in solution and other polluting matters are converted into harmless compounds by bacterial action. These filter beds are constructed in two units each 720ft. long and 125ft. wide, their capacity being 32,650 cubic yards, and their total area 4 acres. In order to ensure a uniform rate of distribution of the tank effluent over the surface of the filtering material, the effluent is drawn from two feed troughs extending the whole length of each bed into travelling distributors, from which it is sprayed over the whole surface of the clinker, the distributors being automatically driven by wire ropes actuated by two small electric motors and reversing gear situated in motor houses at the end of the beds. Each motor is of 4 B.H.P., and operates six distributors, which are automatically controlled by switchgear in the pumping station, so that the number of distributors at work and the rate of treatment on the bacteria beds is always in accordance with the number of pumps in action and consequently with the rate of flow to the beds.

After passing through the filtering media which is 5ft. in depth, the purified effluent is collected by a system of under drains constructed in the concrete floors, and is discharged by main effluent channels into two humus tanks. These humus tanks consist of two circular upward flow tanks of the Dortmund type, having a total capacity of 134,000 gallons, and are intended to remove any flocculent or other matter which may have passed through or come from the filters. The final effluent from these tanks flows by gravitation through the main effluent conduit to Western Pool.

During wet weather when the rate of flow exceeds the volume that need be treated on the bacteria beds, viz., three times the dry-weather flow, the storm water is diverted by a storm overflow weir to the storm water tanks constructed in connection with the first instalment of the works. A new Venturi flume recorder has been installed to measure the quantity of water passing over this weir. As, however, these tanks are not large enough for the treatment of the whole of the storm water that may be discharged, two additional tanks with a total capacity of 500,000 gallons have been constructed to deal with the excess. The storm water is lifted into these tanks by the pumps previously referred to, which are arranged to start automatically as soon as the rate of flow is greater than can be efficiently treated in the storm water tanks provided in the first instalment. The new storm water tanks are situated close to the river Wandle, and have been constructed at such a level that the tank effluent can be discharged by gravitation to the river at all times.

The sludge from all the tanks included in the second instalment of the works gravitates to a sludge well situated at the new pumping station, and is then pumped back to the sludge press house, where the moisture content is reduced by pressing, to enable it to be readily handled for transport. The press house has been extended and four new presses, each of 30-cwt. capacity, have been installed to deal with the additional quantity of sludge collected in the new settling tanks.

The new works have been completed in two years, at a total cost of about £115,000, which is well within the amount of the engineers' estimate. The work has been carried out under the immediate supervision of the resident engineer, Mr. E. FitzRoy Wilson, assisted by Mr. E. J. Ettles. In addition to the plan on this page, we reproduce four views of the new works on page 596.



"The Engineer" Swain Sc.

General Plan of the Completed Wandle Valley Sewage Disposal Works

Credit in Industry.

By J. GIBSON JARVIE.

Ninety-nine per cent. of people do not understand credit. You have got to get into your minds exactly what credit is and to do so you have to go back a little in the history of this country. Credit can roughly be divided into two parts—credit for production and credit for distributive purposes, *i.e.*, credit for consumption. Credit for production has always been regarded as perfectly respectable. I am probably right in saying that most of you here to-day would not hesitate to take credit in making purchases of plant and raw materials, but there are perhaps some who would hesitate to extend credit to their customers. In the old days in England industrial society was mainly divided into two parts, employers and employees. The employers, to a considerable extent, were members of families established for generations, and the bulk of the profits went into their pockets. The employees got their wages, but they had no financial interest in the business. Then the joint stock company came into existence, but still that difference persisted. To-day, a great many public companies are controlled by people who do not own them. In many cases the employees are part owners. You can see for yourselves that in the early days of industry the question of credit had to be viewed from an entirely different standpoint. In those early days the merchants and manufacturers had credit and they used it very intelligently. But their workers did not have any credit. They paid cash and simply tightened their belts when times were bad and carried on. And in those days, demand always exceeded supply.

Coming now to the present day, an entirely new problem has arisen—distribution of the things we produce ; the need of credit for distribution, the need of credit for consumption purposes. And this because supply now exceeds demand. In the old days, distribution credit was not regarded as quite respectable, but there are more and more people beginning to realise that credit for distribution is a perfectly legitimate form of credit. That conclusion is being forced on them by the actual conditions with which we are faced to-day. In pre-war days our problem was production. In every manufacturing country demand exceeded supply. That position has

---

[*] A luncheon address to the British Engineers' Association, on November 12th. The author is chairman and managing director of United Dominions Trust, Ltd.

been entirely reversed. The whole position is changed. It was being changed gradually, but the war made the change acute. Developments took place during the war that normally would have been carried on over thirty or forty years. Our problem is essentially a different one from the one before the war. It is the pre-war problem reversed. Production now scarcely concerns us. The bounty of Nature, science, better methods, mass production and native genius have combined to give us everything we can use or dream of using and we have not the knowledge of how to use them. That is why distribution credit has become so important a problem. I do not want to suggest that credit will solve all our problems. It will not. There are other questions and problems to be solved—tariffs for instance—and particularly in agriculture. There is the question of hours of labour.

Whether we like it or not hours of labour will have to come down and wages will have to go up. We are gradually approaching the point where the big division between employers and employees has got to be narrowed. In the old days the employers received the bulk of the profits from industry; that position must be altered. I am not suggesting that employers whose brains have built up an industry should have less of the rewards of the industry but that the employees will have to have more. We seem to have got beyond the time when the only ambition was to establish large fortunes and found families. In my youth in Scotland I can remember it was the desire of every man who went out to work so to build his own life that things would be a little easier for those who came after him. The great desire even of the labouring man was to leave his family and sons better off. To-day there is not the same incentive, nor is there the same reason; social conditions have changed. The economic position has entirely changed. The great gap between production and consumption must be bridged. It exists only because we have not the machinery for distribution. The system has not been adapted to modern needs. In principle it is fundamentally wrong, and to my mind it is a damnable thing, that there should be any restriction of production under the mistaken idea that it is going to help us to be wealthy. It is a perfectly childish proposition and should not be entertained for a moment. But it will have to be tolerated and entertained if business men do not get down to the fact that old methods have to be altered and the new facts faced.

We have to tune our minds to new ideas. The Macmillan Commission recognised that credit had become a very important thing, and the Report of the Commission speaks of the importance of utilising credit for consumption purposes. I insist that unless we wisely use credit we cannot recover. Credit alone will not bring prosperity, but it is a most important part of the equipment for recovery. If you use credit for production purposes you must logically use the same amount of credit for consumption purposes. That holds good now, though it did not before the war. Then, as I have said, demand exceeded supply; to-day, that is reversed. We have the means of production, greater production than ever before; new methods and conditions have given us that. If we have used credit to bring about this production we must use credit in order to distribute it. Credit is merely a means of exchanging one kind of wealth or service for another kind. It is nothing more than a tool, but it is a most important tool, and it must play a great part in the modern economic system.

There is one type of consumption credit which is perhaps more discussed than any other. For that reason, I shall speak of it. I refer to instalment selling or buying. In the company of which I am chairman, we have financed a large volume of this class of business. Quite frankly, we do it to make money, but also to establish certain principles. In discussing hire-purchase, at once the average man thinks of debt in the sense that it is an obligation on the part of a person who had no right to undertake the obligation. But he is probably quite wrong. If it were true, then the unwise use of hire-purchase would bring its own corrective. The people engaging in it and those financing them would make losses and eventually go out of business. After all, what is hire-purchase? It is merely a means of exchanging certain goods for certain other goods. That is all, and through hire-purchase there has been a lot of real wealth created in this country. During the last fourteen years we have financed the disposal of goods to the value of between £30,000,000 and £40,000,000. Most of these goods were not only durable, but productive in one sense or another. Definitely a great many have reproduced many other kinds of wealth. How, therefore, can anyone suggest that that is bad or that it is unsound business? It has done what we are all striving to do; it has increased business, wealth, and the amenities of life.

Credit is a most valuable tool for that purpose. I claim to have some experience of this, and my company's records of collections over that period show that the position has been so good that losses have not exceeded about one-tenth of 1 per cent. Does not that figure speak for itself? What has been the result? You have small people scattered all over the country who have now assets and capital goods they would not have had otherwise. Do not regard debt necessarily as a bad thing. I should regard my life as wasted from the commercial point of view if I could not incur obligations. The person who gets into debt to-day is usually a credit-worthy person, and the man who boasts that he "owes not any man" may be a debit to the country to-day. We cannot afford such men. If a man has credit and fails to use it wisely, then he is failing in some portion of his duty to himself and to the country. And the country in these times through which we are passing cannot afford that any asset, however small, shall lie idle. It is a perfectly logical statement. Hire-purchase is not a matter of some poor person getting a wireless set or a sewing machine; much the larger proportion of hire-purchase business concerns people whose credit standing cannot be questioned; people who have capital assets already, who own stocks and shares. It also concerns quite important kinds of merchandise. Hire-purchasers have credit, and they realise that it is easier to sell an investment—which they perhaps would have to do in order to make the desired purchase—than to replace it. They, therefore use their credit.

The point is that for every man and for every company there is a figure beyond which it is not convenient to draw a cheque; there is always a figure which is a man's or a company's maximum. But divide it into monthly or quarterly payments and it is an entirely different proposition. In the meantime, you have got the goods, and if they are productive goods, as they are in many cases, they may pay for themselves. I could quote endless cases where merchandise bought on this basis has within the time arranged for payment, paid for itself, and in the end the buyer has a capital asset standing at nothing in his balance sheet. That is very important. Some critics of hire-purchase, unthinking people, dear old ladies who deal with the big stores, and so on, say that hire-purchase is a dreadful business, a direct incitement to extravagance. They talk of encouraging the thriftless, and that sort of thing. Such people are responsible for a good deal of the ignorance on the subject, and they forget that often they owe their grocers, or butchers, or jewellers, money which is frequently overdue and uncollectable. They forget that spending may sometimes be wise and economy unwise.

I discussed this question once with a "cash" tailor. The average account on his books was outstanding eight or nine months. He had the names of people who had had suits for two years without paying. And yet there are people who would argue against this system for clothes! That tailor would be infinitely better off if he had sold on the instalment system. He could at least have budgeted his position. He would have been in a much healthier state financially. Again, I meet firms who say, "Why should I do it? It is undignified. If any of my customers come along I do not mind giving them credit." I would suggest to you, in your own companies, to take the trouble to examine your accounts over the last five years. Examine for yourselves how many of these supposedly thirty-day accounts have been paid on anything approaching the due date.

How many of these thirty-day customers have not paid for sixty or ninety days or more? Figure out a reasonable interest for the period involved and see what it has cost you, to say nothing of the fact that while the accounts were outstanding it was impossible for you to budget with any degree of accuracy. Far too many business men do not look into their accounts from this point of view.

I recall a certain firm making a certain class of machine which was suited for a system of deferred payments. I tried hard to persuade the chairman to sell on hire-purchase contract or on a deferred payments contract (there is an important difference between the two). I spent a long time in trying to show him that it was a perfectly good way of doing business. Finally, he promised that if any customer came along and asked for credit he would remember me. That was as far as I could persuade him to go. That did happen, and we put through one transaction. Within twelve months we handled a large volume of business for that concern. That chairman realised at least the value of organised credit, for most of that was additional business he would not have had otherwise. In every line of business there are potential customers who can pay if they are given time. Do not forget also that due to the diffidence which is characteristic of the British people, the man who is worthy of credit too seldom asks for it. It is the untrustworthy man who so blatantly asks for credit. You will always get the cash customer anyway, but if you "sell" on credit you will get a class of customer that you may not have now and whom you perhaps never will get unless you definitely sell on credit.

I am stating facts because I have compared the methods of different companies in the same line of business. One merchant or manufacturer sells on credit. He does not worry about the cash customer, but definitely offers credit, and he has a big business. Another man accepts a credit customer if he comes along, but does not seek credit business. The chances are he is doing a smaller business. One sees it constantly. In these days many companies in this country find it rather difficult to get along because of the bad years. Their capital is tied up, their assets are in a frozen condition. They could do business if they procured new equipment or plant. This is a type of concern where credit could be used. And credit can be extended to an almost unlimited amount if soundly conducted. There need be no undue risk in it at all. Every case must be considered on its merits. There is a tremendously big field, a wide open field, and British industry will not recover unless our merchants and manufacturers take advantage of it. Our people are diffident in seeking credit, so it must be offered. Do not merely give credit; offer credit.

Take the case of the United States of America. America is quoted as the classic example of the over-extension of credit. I will say right away, and I do not think informed criticism will contradict me, America has not overdone the credit system.

Quite recently I met a vice-president of a most important banking company in America, a company which finances hundreds of millions of dollars of credit business, and he told me about the troubles there and of these abnormal times. The experience of his company has been amazing—at least it seems so—in the circumstances. Repossessions of merchandise financed during the last twelve months are only one-fifth of the repossessions in the previous year. The collection record is at least as good as it has been over several years in spite of the times they are passing through. The company also had a large business in Germany, covering transactions in motor cars and machinery, with about 30 million Reichmarks outstanding a year or two ago. They decided to cut all their foreign entanglements, and they have liquidated to about 1 million outstanding to-day. The normal reserves they have set up are more than sufficient to take care of the losses. Even in Germany, therefore, in spite of conditions, the private German citizen and the small and large German company who bought on the instalment system have paid and are paying their debts normally. From 30 millions to less than 1 million in two or three years! I ask you to give these facts your serious consideration.

After all, money is merely a means of exchange; credit is the same thing only it is more elastic. It can give you bigger business and a better organised business financially, because it can be financed on what is, for all practical purposes, a cash basis for you. That is—credit for your customers, cash at once to you. You can procure a new class of customer and a sound class of customer. There is much business to be done if you will only seek it out and do it.

Napier (N.Z.) Harbour Development Scheme.

A big development scheme has been undertaken in connection with the Napier (Hawke's Bay, New Zealand) harbour scheme. The total expenditure on the complete programme adopted, which will take several years to carry out, amounts to £406,000, the interest and sinking fund for which can be provided from the Board's funds by adding 1s. per ton to the wharfage charges on all cargo (inwards and outwards) for a period of 4½ years, and without the necessity of striking a rate upon land over the harbour rating district. All work, wherever possible, will be on a contract basis, and the 200 to 300 workmen engaged over the period of the contract will be employed full time at standard award rates of pay.

It is confidently anticipated that, apart from the increased trade these facilities will attract, and the more efficient mode of handling Hawke's Bay export and import cargoes, the saving to the Board and the people of Hawke's Bay, once these facilities are provided, will amount to some £70,000 annually, which saving will be increased as wharfage charges are reduced and Napier is made a free port.

The intention is, subject to the approval of the Loans Board, to make, first, a commencement with loan moneys already authorised, by lowering the foreshore (raised 7ft. by the great earthquake of February, 1931), carrying out reclamation works, laying out a new railway yard, starting breakwater extension, and carrying out the necessary dredging for and the erecting of a new timber wharf.

This timber wharf is intended to take the lighterage traffic, and also coastal steamers, if desired, until such time as berthage for overseas vessels is provided, and will be 350ft. in length by 50ft. in width. It will be a substantial job, stiffened with raking piles, flush decked, and carrying four lines of rails. All piles will be sheathed in copper. Both sides will be dredged to 30ft. below low water, so that by later extending the wharf two admirable loading berths for overseas steamers will be provided.

The remainder of the scheme includes rather extensive dredging, the extension of the breakwater by at least 400ft. to afford the requisite shelter, and the erection of a large reinforced concrete wharf, complete with cargo sheds. Dredging will be carried down to a depth of 35ft. L.W.O.S.T. on each side of this latter wharf, thus providing berthage for two of the largest overseas vessels trading to New Zealand, and the structure itself will be 800ft. in length by 181ft. in width. The dimensions of each of the two wharf sheds will be 300ft. by 75ft.

As mentioned previously, the earthquake had the effect of raising the harbour bed by about 7ft., with the result that the deck of the Glasgow wharf is now 16½ft. above high water. The new wharves, however, will be built to a height of only 7ft. above high water level. The breakwater harbour has, through the raising of the breakwater and the formation of spending beaches around the foreshore, greatly benefited by the earthquake, in so far as range within the harbour is concerned, and offers far more secure berthage than heretofore, vessels now commonly tying up with their own lines. With added protection through breakwater extension, it should prove an excellent artificial harbour.

To carry out the above programme of works, the Board intends to raise the sum of £395,000, plus an additional amount of £11,700 for maintaining the Inner Harbour until such time as the first new wharf is built.

BOOKS OF REFERENCE.

Motor Ships of the World and Motor Shipping Register. Fourth issue, edited by A. C. Hardy. London: Sampson Low, Marston and Co., Ltd., 100, Southwark-street. Price 15s. net.—The fourth issue of this annual reference book of motor ships and oil-electrically propelled vessels, shows by its increased number of pages the large number of oil-engined ships which have been added to the merchant fleets of the world during the last eighteen months or so. While the handy arrangement has been retained, giving the name, owners, size, and particulars of main and auxiliary machinery for each ship, it has been possible to add a number of useful particulars which have been missing in earlier issues, and, with the co-operation of shipbuilders and engine makers, to bring all returns up to date. A useful feature of the book is the separate tabulation in the register of motor tankers, oil-electric ships, and motor ships with geared drive. The register, which now contains representative illustrations of modern motor ships, may be recommended to all interested in the progress of the motor ship. It definitely indicates a trend in the direction of large cargo liners, several of which have recently been placed in commission.

Minerals Year Book, 1932–33. Washington, U.S.A. 1933. Price 1·25 dollars.—This new year book is published to supersede the various publications issued from time to time by the Bureau of Mines, and the *Mineral Resources of the United States*, which has been issued annually for some fifty years. It contains some 800 pages and is divided into four sections. The first is a Review of the Mineral Industry, and is followed by "Metals," which includes a large number of tables and statistics of metals, their production, consumption, and, in most cases, their average yearly price in America and other countries. The metals dealt with include gold, silver, copper, lead, zinc, iron, mercury, manganese, tungsten, tin, radium, arsenic, &c. The third part of the volume deals with Non-Metals, including coal, petroleum, asphalte, stone, sand, clay, salt, talc, mica, &c. The book concludes with a section on mine safety.

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

RESEARCH ON STEELS FOR HIGH TEMPERATURES.

Sir,—I have read with great interest the leading article in last week's issue of your paper, and your report on a Conference recently held in London for the purpose of securing continued financial support for carrying on the valuable researches now in hand on steels and steel alloys suitable for higher temperatures.

I have for many years been an advocate for higher temperatures for steam power plants, believing that it is easier to raise the thermal efficiency by means of temperature than by increase of pressure. At a later stage research may enable us to increase both temperature and pressure, and gain still higher efficiency.

It was not difficult in the past to find sympathetic friends agreeing that the idea was good, but when it came to actually building a plant, no one would take a commercial risk without imposing impossible guarantees from the manufacturer. Here was a lack of co-operation, and development was retarded till five years ago when Mr. Alex Dow, president of the Detroit-Edison Company, U.S.A., came to the rescue by ordering from my company a 10,000-kW turbo-generator running at 3600 r.p.m. to operate at a steam pressure of 375 lb. and a steam temperature of 1000 deg. Fah. The turbine plant was duly designed and manufactured in Rugby and shipped to Detroit. The superheater was supplied by B. & W., New York, and is of the radiant type.

In designing the steam turbine for this relatively high temperature I was greatly assisted by the research work which had already been done by the B.E.A.I.R.A. Research Committee at the National Physical Laboratory, and our own tests in Rugby on the creep limit of various steels and steel alloys for temperatures up to 1100 deg. Fah.

It may interest your readers to know that this plant has been in commercial operation for the last two years, and for 8000 hours has been in operation with a load of 10,000 kW and steam temperature of 1000 deg. Fah. Obviously, some troubles were expected, and also encountered, at this high temperature; mostly caused by creep. On the whole, the troubles have been less than expected, and not of a deterring or serious nature, but confined to accessories.

Two papers are being read this week in New York before A.S.M.E. on this plant, one dealing with the various materials used in the construction of the plant, and the other one giving thermal performance. From the latter it will be seen that energy consumption in B.Th.U. per kW-hour is reduced from 11,600 at 700 deg. Fah. steam temperature to 10,700 at 1000 deg. Fah. steam temperature, or a gain of 7·75 per cent.

That the turbine efficiency is improved with the higher temperature is shown by the following figures:—

At 700 deg. Fah. steam temperature, combined turbine and heater efficiency, 76·7 per cent.

At 1000 deg. Fah. steam temperature, combined turbine and heater efficiency, 79·5 per cent.

—a gain of 3·6 per cent.

These test results may to-day be considered on the low side, but their relative values are important.

When the plant was designed, simplicity was aimed at; efficiency had to take second place to safety at the high temperature. These results are most encouraging and indicate that it will be worth while to carry on the research work now in progress at the National Physical Laboratory.

Frederick Samuelson.

December 6th.

POWER TRANSMISSION FROM NORWAY TO GERMANY.

A scheme for the electrical transmission of power from Norway to Germany has long been projected, and was discussed at the World Power Congress in Berlin a year or two ago. With the co-operation of the two leading electrical manufacturing firms in Germany, Swedish and Norwegian interests then formed a company under the title of the Norsk Kraftexport, A.S., for the purpose of studying the problem, and at the annual meeting of this company in Oslo on November 30th, when engineering representatives of the Berlin A.E.G. and the Siemens interests were also present, the question of Norwegian supply to Germany was raised in connection with an invention which has been devised by a Swedish engineer (Herr Baltazar von Platen). This engineer claims to have invented a machine for the long-distance transmission of energy by means of the use of very high-tension continuous current.

Herr Bernard Ell, chief engineer of a Swedish cable manufacturing works (Sieverts Kabelverk, of Sundbyberg), presented a report on the new machine at the meeting of the Kraftexport company. According to the *Goteborgs Handels och Sjofartstidning*, Herr Ell stated that the machine in question is constructed on the collector system, and the progress made with it has so far proceeded that it is now possible to build machines for high-pressure continuous current of a capacity of 60,000 kilowatts and a tension of 300,000 volts. On his part, Herr Ell submitted that there would be no difficulty in constructing cables for 500,000 volts for the proposed transmission of power from Norway to Germany, and expressed the opinion that the cables in the first place should be laid direct from Norway to Denmark as continuous-current cables. While there would be no difficulty in producing the necessary cables, he considered that difficulties would arise in laying them, and for this purpose a special ship would have to be built.

Canadian Engineering News.

(By our Canadian Correspondent.)

Montreal Water Level Problems.

Periodic drops of the harbour water levels to a low mark constitute a threat to Montreal's position as one of the world's first-class ports, and for that reason the study of this problem and of its most effective solution is being intensified in Federal Government circles. In the near future a 35ft. channel from Montreal to the sea will be completed, but this boon to St. Lawrence River navigation would be of little value if the safe movement of vessels to and from the berths in the harbour could not be assured. One of the anomalies of the present situation is that the very deepening of the channel to Montreal from the sea has to an extent aggravated the problem of water levels in Montreal Harbour. The deepening and the accompanying acceleration of water flow down the St. Lawrence from Montreal has obviously had an adverse influence upon levels in the harbour. The serious water level conditions during recent weeks has prompted those most deeply concerned to turn to the report of Sir Alexander Gibb, written two years ago, on Montreal's harbour facilities and the channel improvement down to the sea. After referring to the great dredging programme, now nearing completion, Sir Alexander Gibb had this to say about the channel and its relation to harbour levels at Montreal: "It is now clear that dredging of itself will not secure, except at prohibitive cost, a permanent and dependable 35ft. channel. I feel strongly that the problems of the St. Lawrence are too difficult, complicated, and far-reaching, and that its control and regulation will involve too many considerations and too heavy expenditure for it to be left either in the hands of one department or divided among a number." Since then the dredging programme has been almost completed, but a satisfactory solution of the problem of water levels in Montreal Harbour has not yet been found. As a result of the report of the Haskell Commission, made in 1915, a series of weirs or dams was built by the Department of Marine in the islands at Sorel and above that port. That work has had the effect of raising the level of the river at Sorel by 1½ft., and the Montreal Harbour level by at least 6in. This latter result, however, is far from solving Montreal's problem. Another plan proposed was the building of a dam or weir at the foot of Lake St. Peter. Still another called for a dam further down the river, and a third was the erection of some control works at the foot of Lake Ontario. All these schemes have been given study by Government officials and much valuable information has been gathered.

Municipalisation of Electricity.

Municipalisation of electricity in the province of Quebec, where power is wholly distributed by private companies, is now being widely discussed and the question is likely to develop into a spirited controversy at the next session of the Quebec Legislature. Already two municipalities, St. Hyacinthe and Quebec City, have decided to submit the matter to property owners in the form of referendums next January, and the question is also a live issue in Montreal, where a contract with the Montreal Light, Heat and Power Consolidated for the lighting of streets and public buildings will soon have to be renewed or rejected. During the last two sessions of the provincial Legislature, Government members have voted against the demand of the City of Quebec for authorisation to municipalise electric services. Since then, events have occurred which seem to show that the people favour more than ever the municipalisation movement. A group of Montreal members is preparing to ask the Government for the creation of an independent Commission to investigate the question, with instructions to report to the Legislature with suitable recommendations which could be acted upon before the end of the coming session. From the provincial point of view, the situation is complex, for while the cities and towns tend towards municipalisation, the rural sections clamour for an extension of electric transmission lines throughout the province, and companies distributing electricity claim that they cannot satisfy all the demands in the province, especially in sparsely populated communities, without a heavy loss.

St. Lawrence Channel Deepened.

Government engineers have completed part of the work of deepening and widening the North Traverse Channel, that section of the St. Lawrence to the east of the Island of Orleans. This waterway, which eliminates the more difficult section of the river known as the South Traverse, has been dredged to a depth of 32½ft. at low water, and provides a channel 500ft. in width. The completion of this further stage in the development of the St. Lawrence removes, therefore, another possible hazard to navigation. The ultimate objective for the North Traverse Channel is 35ft. at low water and a width of 1000ft. Dredging operations in this section of the river commenced as far back as 1911. Six years ago, on June 1st, 1927, the North Traverse Channel was declared available for navigation by vessels drawing down to 25½ft. at all stages of the tide, and by craft of deeper draught at all stages other than extreme low water. It was buoyed throughout its length, and all pilots were fully instructed on the aids to navigation. The project at that time was termed prodigious. In order to permit of ships drawing down to 30ft. to navigate the 10-mile stretch at all stages of the tide, it was necessary to remove an additional 550,000 cubic yards of material, while an estimate of 3,743,806 cubic yards was given as the amount that had to be dredged from the channel before a depth of 35ft. and a width of 500ft. could be attained. During the last season of navigation, two dredges worked 171 and 99 days respectively, completing and cleaning up the channel to a width of 500ft. They also commenced widening the "cut" to 1000ft. These craft removed 237,714 cubic yards on the 35ft. project, and 315,071 cubic yards of material were taken out in cleaning up the waterway. Figures for this season are not yet available. Government engineers state that a total of 127,135,808 cubic yards of material will have been removed from the ship channel between Montreal and the sea when the full 35ft. project has been completed.

Electric Railways.

The traffic of electric railways in Canada, which is composed largely of urban street car traffic, has been declining, and during 1932 five systems, including two inter-urban lines, ceased operation. One of these, the Brantford Municipal Railway, substituted an omnibus service for three months, but resumed operation again early in 1933. During the year 720,468,361 fare passengers were carried, which was a decrease from the 1931 traffic of 77,637,359 passengers, or 10·8 per cent. The greatest rate of decrease was on the small systems carrying less than two million passengers per annum. These showed a decrease of 29·1 per cent.

Cement-coated Nails.

Tests carried out at the Forest Products Laboratories of the Dominion Government have shown that cement-coated nails have from two to three times the holding power of similar types which have not been coated, depending on the density of the wood used. In woods of low density such as pine, basswood, and spruce, the ratio of holding power of the cement-coated nails is approximately three to one, while in heavier woods, such as birch and elm, the ratio is approximately two to one.

Nickel Production.

Finally revised statistics on nickel production in Canada in 1932 show an output of 30,327,968 lb., valued at 7,179,862 dollars, as compared with 65,666,320 lb., worth 15,267,453 dollars in 1931, and 103,768,857 lb., valued at 24,455,133 dollars in 1930. The 1932 production represents a decline of 53·8 per cent. in quantity, and 53 per cent. in value from the preceding year, and 70·8 per cent. in volume and 70·6 per cent. in value from 1930. During the first six months of the present year production of nickel amounted to 22,808,434 lb., as compared with 21,162,786 lb. for the corresponding period of 1932. The greatest improvement was shown in May and June of this year.

SIXTY YEARS AGO.

Quite recently it was hinted in pretty plain terms by a member of the Government that if the users of our roads did not of their own accord take effective action towards securing a reduction in the number of road accidents and fatalities the Government would be compelled to take drastic steps to enforce that end. The occasion is not one which justifies the adoption of a pharisaical attitude on the part of the railways, rightly proud though they may be of the relative safety which they offer the travelling public. If they feel tempted to express pious thanks that they are not as the roads, they should remind themselves that exactly sixty years ago they were in precisely the same position. There had been a rapid recurrence of numerous and fatal accidents on the railways. The public had become somewhat alarmed, and Mr. Chichester Fortescue, the Secretary to the Board of Trade, had addressed a circular letter to the companies, calling their attention to the facts. In that letter he urged that more caution in the working of the railways was desirable and hinted that unless his suggestions were acted upon the Government would very probably interfere to enforce steps designed to promote safer travelling. In a leading article on the subject in our issue of December 19th, 1873, we were hardly polite to Mr. Fortescue. His threat of Government interference was, we considered, an idle one, and amounted largely to "empty vapouring." Nevertheless we were equally severe with some of the companies over certain statements and lines of argument made and followed in their replies to Mr. Fortescue's letter. Mr. Laing, of the London and Brighton Company, and, to a lesser extent, Mr. Castleman, of the South-Western, had, we thought, made out good cases for their railways against the official criticism. Their replies stressed the fact—a fact which we fully accepted as true—that the railways in the South of England were almost exempt from casualties. It was easy, we thought, to see why the southern lines should be so happily situated in this respect. They had little goods or mineral traffic except light parcels for the Continent, and coal. Their trains ran nearly at a uniform speed and there was a minimum of shunting. They had few extended runs and they undoubtedly enjoyed the advantage of drawing their servants from the better educated population of the South. With the reply sent by Mr. Moon, of the London and North-Western, we expressed disagreement and discontent. He argued against the adoption of the continuous brake that it was still uncertain whether it was applicable to and would prove satisfactory on his company's 4000 passenger vehicles, and that in any event the rapidity of invention rendered it desirable to wait in order to see what improvements would be made. Mr. Castleman also opposed the adoption of the continuous brake on various grounds, the chief of which was that it would have a bad effect on the tires, wheels, axles, and rails. Our reply to these arguments was that, while it was necessary to exercise caution in the adoption of new inventions, a point could be reached at which caution degenerated into criminal cowardice. Mr. Moon and Mr. Castleman, in view of what had recently been done in the United States in the way of applying a system of continuous brakes—we were obviously referring to the Westinghouse system—were, we held, very much too cautious for the public good. Other points affecting the safety of railway operation with which we dealt were defective signalling systems and congestion of traffic. Very radical changes, we felt certain, would have to be introduced at no distant date. The most necessary of them all, we argued, was the doubling of the main lines in order that goods and passenger traffic might be worked on separate systems of permanent way. Not only safety, but the continued prosperity of the country, demanded that improvement.

Railway and Road Matters.

A traffic officer of the London, Midland and Scottish Railway, speaking at Holyhead last week, said that it was proposed to accelerate the Irish mail trains by fifteen minutes.

What, when introduced last May, were known as "summer" tickets, but which might equally and more fittingly be called return tickets, are to be continued during 1934. In making this fact known the railway companies intimate that the results have indicated the desirability of a longer experimental period.

We now learn that the railway and works in the urban district of Hazel Grove and Bromhall, mentioned herein on December 8th, in relation to the Bill deposited by the L.M.S. Railway, will join the Stockport and Buxton branch and the New Mills and Heaton Mersey main line. These lines cross each other on the west side of Stockport.

The "Royal Scot" train which toured Canada and the United States will be on exhibition at Euston Station over the present week-end. The engine and eight coaches will be thrown open to public inspection at No. 6 platform, Euston, from 3 p.m. to 10 p.m. on Friday (December 15th), 10 a.m. to 9.30 p.m. on Saturday, and 10 a.m. to 10 p.m. on Sunday (December 17th).

The landslide on the Cambrian coast, near Fairbourne, last March, and its sequel in a fatal railway accident, will be remembered. The Merioneth County Council proposes, as a consequence of that accident, to divert the road, but at a meeting of the Council on December 6th it was reported that the Ministry of Transport had refused to make a grant towards the work, and that the railway company had declined to rebuild and maintain the retaining wall. The facts were recorded in The Engineer of July 14th last.

The extensive alterations that have been made at Paddington Station, including the absorption of Bishop's-road, have led to the station being equipped with power signalling. There are three signal-boxes, Westbourne Bridge, Paddington Arrival, and Paddington Departure, which contain 88, 184, and 96 levers respectively. The frames have the interlocking electrically operated, as is now become the practice after eighty years' use of mechanical interlocking. The signal contractors were the General Railway Signal Company, Ltd.

On Tuesday, December 12th, the London, Midland and Scottish Railway announced that a works and rolling stock programme for 1934 had been authorised, which will involve an expenditure of no less than £8,400,000 on major replacements and improvements. The programme includes the construction of 232 locomotives and 159 locomotive boilers, together with 674 carriages and 5365 wagons. In addition, the company will renew 500 miles of permanent way, representing 80,000 tons of rails, all of which will be ordered from British steel manufacturers. The announcement of this large development programme follows the recent allocation by the L.M.S. of orders with British manufacturers for 100 new locomotives and 2000 freight wagons for express services, which was recorded in a Journal note of December 1st.

There were three serious railway accidents last week. On the evening of Wednesday, the 6th, an up fish train, running between Raskelf and Alne, on the London and North-Eastern Railway, north of York, caught up and collided with a goods train. The down main line was fouled as a consequence of the collision and the 4 p.m. express from King's Cross to Newcastle ran into the obstruction. There were no personal injuries. During a dense fog on the morning of Thursday, the 7th, an electrically operated passenger train, when entering Altrincham, M.S.J. Joint Railway, collided with a standing train. The driver of the arriving train was killed. On the evening of Friday, the 8th, a goods train was being shunted off the down line into a siding at Broadheath, L.M.S. Railway, when the 5.15 p.m. express from Manchester to Liverpool ran into it.

One of the economies in railway operation that war conditions compelled was the common use of wagons. When a wagon belonging to one company passed on to the line of another company the latter could not use it for any other purpose than for a load to the owning company, and frequently it had therefore to be returned empty. By the common use then introduced the wagon could, if necessary, be used for a consignment in any direction. That has been retained and, with only four owning companies, is now much simpler. The same arrangement applies to the tarpaulin sheets for covering the contents of wagons. From time to time a census is taken of the wagons and sheets to be found on each railway, so that each owning company may be credited with the number the other companies have on their lines. It was such a census that we referred to in our Seven-day Journal for December 8th.

The Railway Returns for 1932 show that during that year 271 locomotives, 837 carriages for steam-worked trains, and 6770 wagons were renewed, as compared with 380 locomotives, 1008 carriages, and 9398 wagons renewed in 1931. The list includes also 112 electric rail motor vehicles and 136 carriages for electrically operated trains; none of this class appeared in the 1931 Returns. The number of locomotives under or awaiting repair at the end of the year was 6·69 per cent. of the total stock, as compared with 6·24 per cent. in 1931. It is observed that there was a considerable increase in the number of wagons undergoing or awaiting repair at the end of 1932. The Returns also record that the hours during which locomotive power was in use decreased by 5·14 per cent. Whilst there were only small decreases in the passenger train hours and shunting hours, there was a decrease of 10·28 per cent. in the freight train hours and of 6·16 per cent. in the freight shunting hours. The passenger train miles per train hour increased from 14·72 in 1931 to 14·84 in 1932 and per engine hour from 3·61 to 3·70. Freight train miles per train hour increased from 9·11 to 9·58 and per engine hour from 3·61 to 3·70. These particular figures, we would observe, are indicative of the average speed, and it is gratifying to note that the Returns observe that the figures for 1932 are, in each case, the highest recorded since these figures became available—in 1920.

Notes and Memoranda.

According to Mr. H. J. Gower, of the Streets Committee of the City Corporation, London, the cost of rubber paving is four times that of wood or asphalt.

At the Congress of the British Institute of Radiology, Dr. A. Bouwers exhibited one of the world's smallest X-ray apparatus, weighing 7 lb., yet being capable of taking photographs in 2 sec.

According to the Dominion Bureau of Statistics at Ottawa, Canadian asbestos producers delivered 16,393 tons of asbestos in August, the highest total for any month since October, 1931. In July 14,531 tons were produced and in August last year 9918 tons. During the eight months ended August 31st deliveries totalled 79,556 tons, as compared with 72,539 tons in the corresponding period of 1932. Exports advanced from 13,490 tons in July to 17,645 tons in August.

Stainless steel has not been seriously considered in America for underground pipes except under unusual conditions because of its relatively high cost. Its behaviour in soils in which the oxygen supply is limited has not been fully determined. The U.S. Bureau of Standards is now testing a variety of iron-chromium alloys in a wide variety of soils. One test by an oil company of an alloy containing 18 per cent. chromium and 8 per cent. nickel showed favourable results in a soil containing sulphates where commercial steel and an alloy containing 5 per cent. of chromium both showed rapid corrosion.

The mechanical properties of non-ferrous metals at low temperatures were recently discussed in a paper by Mr. E. W. Colbeck and Dr. W. E. MacGillivray, read before the Institution of Chemical Engineers. From the work done in the research laboratories of I.C.I. (Alkali), Ltd., it would appear evident that the excellent properties of the copper-nickel alloys, 70–30 brass, and nickel silver throughout the temperature range from 20 deg. to −180 deg. Cent., will make them valuable materials for plant to work at temperatures below zero. These materials have been tested in the annealed state and their large reserve of ductility suggests that it would probably be safe to use many of them in a slightly harder condition.

An example of the troubles which may be caused by temperature changes is mentioned by M. H. Ball in the *Machinist*. A job required close work in machining diameters of about 48in. on brass castings. Trouble was encountered when using a steel gauge. Interchangeability could not be maintained until a brass gauge was substituted for the steel. The brass gauge was subject to the same linear expansion as the work during temperature changes, whereas the difference in the two metals when the steel gauge was used added to the troubles. The difference in the expansion of the steel gauge and the work was 0·0024in. for a temperature range of 20 deg., which was sometimes experienced in the shops.

A pipe-cutting and bevelling machine has been made by the Linde Air Products Company, New York. It consists of a centre rod with three spreading arms, which press against the inner wall of the pipe, holding it in position, with an arm supporting a blow pipe that can be adjusted to the desired angle of the cut. The blow pipe and arm rotate without the use of a crank for quick centring of the device, and by means of a crank when doing actual cutting. This machine will take almost any hand-cutting blow pipe, is readily portable, and is simple to operate. Once centred in the pipe, the operator merely turns the crank causing the blow pipe to rotate evenly around the pipe, making a clean machine-like cut.

According to an extract in the *Chemical Trade Journal*, the chemical resistance of lead can be materially enhanced by the addition of small quantities of copper, antimony, silver, &c., provided that these additives form no eutectic mixture with the lead. In other words, these metals are not to be alloyed with the lead, but to be mixed with it mechanically. They can, for instance, be in the form of shavings mechanically pressed into the lead surface, or they can be coatings formed by electro-deposition. Experiments have demonstrated that lead, over which a thin partial coating of silver has been rolled, has greatly enhanced resistance to hot concentrated sulphuric acid, whilst lead containing the same quantity of silver as an alloying material shows no improvement in acid resistance over the untreated lead.

In the discussion following the reading of his paper on "The Trends of Machine Tool Design," Mr. I. H. Wright said that the firm with which he was connected had been slide grinding for about four years. The examination of ground slides showed that slide grinding was superior to scraping for heavily loaded slides, such as the table for a milling machine. With scraping there was a considerable tendency to scratching of slides, and with slide grinding that did not so readily occur. Before seriously deciding on slide grinding, they had made tests with flat plates under equal conditions of lubrication, planed, scraped, and ground. These were reciprocated thousands of times with a very small amount of oil on them, and the ground surfaces showed very great superiority over either the scraped or planed.

Unfortunately, magnesium is very liable to corrosion, especially when exposed to sea water or moisture. An impetus to its more extended use should therefore follow from the discovery of satisfactory methods for protecting it against corrosion. Some very promising methods for this purpose have resulted from work carried out at the Chemical Research Laboratory of the Department of Scientific and Industrial Research, and were described last week by Dr. Bengough and Mr. Whitby to the Institution of Chemical Engineers. The process has the merit of simplicity, as it consists only in immersing the magnesium materials in a solution of selenious acid or its salts for about 15 min. This results in the article becoming covered with a protective coating of selenium. The value of the treatment, Dr. Bengough pointed out, is likely to be greatly increased by the fact that the coating appears to afford a very satisfactory basis for applying paints which may sometimes be necessary in cases of prolonged or severe exposure. The lecture was illustrated by figures showing the great superiority of this British process over competing foreign processes.

Miscellanea.

It is proposed to expend £22,500 on building a retaining wall in Cowes Harbour, Isle of Wight.

A demonstration plant for the manufacture of "Coalite" is to be erected at Lens, France.

The Sub Nigel gold mine, South Africa, is to put up a new reduction plant, with a capacity of 50,000 tons a month.

The Great Western Railway has ordered 100,000 steel sleepers, weighing 10,500 tons, from Guest, Keen and Nettlefold.

A seam of coal and carbonaceous shale, 77ft. thick, has been discovered at a depth of 117ft. at Driefontein, Transvaal.

A company with a capital of about £200,000 has been formed in Manchukuo for the manufacture of explosives. It will probably secure a monopoly from the Government.

An order has just been placed with Scotts Shipbuilding and Engineering Company, of Greenock, for a large passenger liner, to be equipped with oil engines by the builders.

A competition for the design of a hangar for airships is being held by the section for scientific research, Dirigeablestroy (Civil Aerofleet), Moscow, Russia. The first prize is 10,000 roubles.

There is announced the death of Henry H. Westinghouse at the age of eighty years. He was brother of George Westinghouse, the inventor of the air brake, and was himself a distinguished engineer.

An arrangement has been made between Edgar Allen and Co., of Sheffield, and the Buell Combustion Company, of London, under which the pulverised fuel plants of the latter firm will be manufactured in Sheffield.

It was stated by the Under-Secretary for Air in the Commons that the experiment recently carried out with an Air Force squadron using only petrol produced from British coal had so far given generally satisfactory results.

It is reported in the *Chemical Trade Journal* that a still further extension is to be made to its bromine plant by Palestine Potash, Ltd. Sales of crude potash salts are understood to cover production for several months ahead, two of the principal buyers of this Dead Sea potash being Canada and Australia.

The Budapest city authorities have decided to heat and light the city with the sewage which flows through the drainage system. Mr. Zaits, the city's technical adviser, states that he proposes to erect a giant closed concrete basin, in which the sewage will collect and ferment, thus creating methane gas.

An interesting experiment was recently carried out by the Industries Department of the Mysore State in the erection of a gas plant for generating electric power from lantana charcoal. The experiment yielded satisfactory results, inasmuch as it was found possible to generate electric power at a cost of about 1 anna per kWh.

The Tinnevelly–Tuticorin Electric Supply Corporation has completed the erection of the new electric installation at the Tuticorin power house, and also the laying out of transmission lines in Tuticorin, Tinnevelly, and Palamcottah. The generator and the transmission lines have, says *Indian Engineering*, been tested with satisfactory results.

Exhaustive experiments with a new process of producing petrol from sawdust and peat are being undertaken by the Swedish Government, according to Professor Komppa, the well-known Finnish chemist, who invented the process. The Swedish authorities have granted a subsidy of £8300 for the building of an experimental factory.

According to *Die Chemische Industrie*, there is to be erected at Mazanderan, in the neighbourhood of Teheran, a tar distillation plant, principally for the production of heavy oils for the impregnation of railway sleepers. A considerable quantity of the plant has already been installed, and it is expected that the works, which are near the Schemschak Coal Mines, will shortly commence operations.

Continued low water in the harbour at Montreal with its serious effect upon shipping, has resulted in urgent requests being made upon the Department of Marine for definite action to correct this situation. A proposal has been made to the Department for the creation of a series of low under-water dams along the river between Montreal and the wide section below Montreal known as Lake St. Peter; also for the construction of a dam near the outlet of Lake St. Peter to restrict the discharge of the river at that point.

The Board of Trade has decided that in present circumstances a candidate may be permitted to sit for the written portion of his first mate's or master's certificate on the completion of twelve months' sea service (foreign-going) instead of the eighteen months' sea service (foreign-going) required under the examination regulations as they now stand. A candidate who sits for the written part of his examination and passes will be allowed to take the oral part of the examination after he has completed the full period of eighteen months' sea service.

Striking examples are forthcoming of the time savings that can be effected in the dispatch of urgent loads over long distances by a combined use of air and ocean transport. Recently an express parcel was consigned by air mail and ocean liner from Victoria, British Columbia, to Nairobi, in Kenya Colony. This packet, on its first stage, was flown by air mail to New York. Here it arrived in time to catch the liner "Europa," and after crossing the Atlantic, and when still 600 miles from Land's End, it was catapulted from the liner, with other express mail matter, and flown by seaplane to Southampton. After this the parcel was airborne by Imperial Airways from London *viâ* France, Italy, and Egypt to Africa, duly reaching Nairobi after having travelled 10,000 miles by air and sea in thirteen days. By ordinary transport the journey would have occupied more than a month.

WANDLE VALLEY SEWAGE DISPOSAL WORKS

STEEL TRADE REORGANISATION PLANS.

THE duties of the National Committee for the reorganisation of the steel trade may be classed amongst the more thankless tasks of the world. On the one side it is under the persistent pressure of a Government desiring an achievement which may be claimed as a political success, and on the other it has to compose conflicting trade interests and allay natural commercial suspicions. Set up eighteen months ago to proceed with the immediate preparation of a plan to reorganise the steel industry and to bring it to such a stage of efficiency that it could meet foreign competition in the home and export markets, it was given to understand that the continuation of the newly imposed import duties depended upon its success. In April last it presented a scheme to Sir George May's Tariff Advisory Board which provided a constitution for the steel industry of a most ingenious character. Each branch of the trade was to be governed by its own Association, and there was to be a central body—then described as a Corporation—composed of representatives of the trade Associations. This latter body was to direct the affairs of the industry. The associations of manufacturers, who, in one form or another, were also consumers, were to be bound to each other by a system of interlocking rebates, quotas, and fixed prices, designed to make it impossible for any firm to leave its Association. When the scheme was presented to the industry, it became apparent that there was little hope of securing unqualified support, and as the practicability of the plan depended upon its being accepted by the great majority of those to whom it applied, it was obvious that some of its provisions would have to be modified. The National Committee, therefore, reconsidered its scheme in the light of the criticism it had received, and has now formulated fresh proposals for the consideration of the trade. In the main, however, the original plan appears to have been retained; but readjustments have been made in the representation of certain branches of the industry in order to relieve fears that their interests would be swamped in those of the pig iron and steel-producing industries.

The National Committee is both helped and hindered by the diversity of the interests which it has had to consider, and by the close association these interests have with the steel-producing section of the trade, which, of course, is the rock upon which all the subsidiary industries are built. It is difficult to visualise a central directing organisation that could guard the interests of the steel makers and guide with equal skill and experience the fortunes of such diverse trades as the Welsh tin-plate, the Midland re-rolling, and the engineering industries. At the same time, no reorganisation could be complete were any of these industries excluded. Again, experience has shown that the problem of arranging quotas is beset by difficulties which, in the past, have shipwrecked many promising cartels. Subject to the drastic trade action possible under the Association and rebate proposals, the Committee has relied upon the voluntary principle, and even admits the difficulty of framing regulations which cannot be circumvented by keen commercial minds. This is a wise attitude, since it is certain that only a small proportion of the industry would support an attempt to dragoon by legal force the iron and steel and subsidiary trades into a scheme which its strongest supporters must admit is bureaucratic in inception and construction. Nevertheless, whilst those associated with the scheme avoid talking of compulsion, there must be at the back of their minds the knowledge that if a large majority of the iron and steel trades accept the scheme, it will be possible to obtain powers from the Government to compel the adhesion of the remainder. Obviously, this would be a situation in which neither the Committee nor the Government would care to be placed, as action of this nature might have political repercussions which it would be difficult to estimate. On the other hand, it is highly improbable that a unanimous and cordial welcome will be accorded to any scheme of such a far-reaching nature, since it is not a characteristic of the British industrialist gaily to march along uncharted paths towards a goal which cannot be easily discerned. The Government, of course, has in its hands a powerful weapon in the import duties, and many spokesmen have not hesitated to hint at its use if the steel trade does not, to use a favourite but obscure term, "put its house in order." The removal of the import duties strikes us as being remote in the extreme, and their reduction almost as unlikely. It cannot be denied that the steel industry has taken advantage of the shelter afforded by the protective duties to proceed with reorganisation plans, which, if not so wide-sweeping as the Committee's revolutionary proposals, have an appearance of sound commonsense. Not since the war have our iron and steel concerns been so busy, or have their prospects looked brighter. The Government would naturally prefer to see a larger proportion of export orders in current business, and the National Committee's plans for dealing with the export trade are amongst the most interesting of their proposals. The Committee has taken the view which is frequently urged by economists that if the steel export trade were transacted through one organisation, it would be easier to conduct important business and to maintain prices. There is in existence already the British Steel Export Association, formed a few years ago to handle the steel makers' export business in sections and plates in quantities of 250 tons and over, and it is probable that this organisation will be converted into a company to handle the overseas business of other branches of the trade. It seems likely, however, that the extent of the support it will receive may prove disappointing. The South Wales tin-plate trade, for instance, has its own organisation, the sheet makers have theirs, and few of the re-rollers would care to surrender their own selling methods. In fact, the principle of central selling is not so highly thought of amongst industrialists as it was a few years ago, and it is generally agreed that to be successful such an organisation must be supported by practically the whole of the industry for which it sells, and that the industry itself must be under rigid control. It may be thought that these requirements are satisfied by the scheme; but association in central selling is to be voluntary, and apparently the new organisation will buy and sell as a merchant concern. A proposal that export business should be assisted by an export levy may cause some concern. It is proposed that the levy should be made upon the manufacturers' home business, and be used to cheapen export prices when necessary to meet foreign competition. This at once raises the controversial question of how far it is legitimate to raise home prices to subsidise export business, a question upon which the steel trade itself is by no means agreed.

It will be seen that although the National Committee has with great courage and trouble worked out a scheme of reorganisation, it will be some time before the industries concerned can put it into effective operation, even if it is adopted by the majority of the trade. As we have pointed out, the steel trades have not been idle whilst the Committee has been at work, and although the industries may not have "regimented" themselves according to the preconceived official ideas, greater progress has been made by individual initiative behind the tariff wall than could have been expected in so short a time. It is probably within the mark to say that production has increased from about 45 per cent. of capacity before the import duties were imposed to 70 per cent. to-day. Of even greater importance are the big schemes of expansion and new development which have been undertaken, to mention only Stewarts and Lloyds' Corby enterprise, and Guest Keen's Cardiff plans. The Government has also done its share by spurring on the Committee, and the time has now come when the industry and its Committee should be left in peace to deal with their problems and their reorganisation plan. Considering the long years of indifference with which successive Governments treated the industry, a reasonable time should be allowed for it to effect a reorganisation almost revolutionary in character, as the participants will be bound for a period of ten years.

Invention and Design.

THE story of mechanical progress is mainly a record of the successes of two kinds of men, inventors and designers. The distinction may at times be invidious, for design at its highest treads on the borderland of invention, whereas invention, if it may be judged by the standards of the Patent Office, often requires no more ingenuity than may reasonably be expected of the average draughtsman. There is, nevertheless, an essential difference. What the inventor does is to create something new, which, however imperfect it may be at first, opens up some unsuspected avenue of advance, while the designer strives to attain perfection along lines already laid down. The same type of mind is at work in both cases, but how it works and why it is given to one man to conceive an idea that has eluded thousands of other workers in the same field is, and is likely to remain, a mystery. An idea is, however, but the first step towards an invention. Until it has been translated into some workable device or process it is but the airy fabric of a vision, and of about as much practical use. The inventor is far more than a man who can see visions or dream dreams in an armchair. He must have the art of making his dreams come true, and the courage, devotion and persistence he has to display before natural difficulties can be conquered and the opposition of ignorance or vested interests overcome, are at least as essential to his success as is his fecundity of mind.

It was this aspect of invention which was given prominence in Mr. C. D. Gibb's address as Chairman of the North-Eastern Branch of the Institution of Mechanical Engineers on Wednesday, December 6th. Speaking from personal knowledge, Mr. Gibb sketched some of the manifold problems which Sir Charles Parsons had to solve before the steam turbine was established on land and sea, and he threw an interesting light on the mentality of the great inventor. In the first place, Parsons had the faculty of thinking clearly. He visualised exactly what he wanted to make or to do, and then set about it in a simple and direct manner. Moreover, "while he never allowed himself to be discouraged by adverse fortune, however disheartening, and never admitted defeat, he had the instinct to know when he was 'facing a brick wall' and always planned to get round it or underneath it instead of making a futile frontal attack." Of his persistence in the face of difficulties it is recalled that he spent £25,000 on experiments with high-speed propellers before the "Turbinia" was a success. But another fact not generally known is that, even after the astonishing performance of this vessel, the Admiralty refused to consider the introduction of steam turbines into the Navy unless Parsons would first put up £100,000 for the construction of a turbine-driven destroyer, which sum was not to be refunded until after the boat had successfully passed through her acceptance tests. It was well for the country that Parsons' confidence in his invention was shared by a wealthy and public-spirited man like the late C. J. Leyland, who came forward and took the risk that the Admiralty was unwilling to face. The vessel in question was the ill-fated "Viper," which achieved the unprecedented speed of 37 knots and justified in every way the new method of propulsion before her untimely end in 1901 on the rocks of the Channel Islands. The development of the 36,000-

volt alternator might also have been mentioned by Mr. Gibb as another instance of persistent and costly experimental work culminating in the expense of building an experimental machine which could be offered with confidence as embodying the complete solution of a difficult problem on a commercial scale. These few instances give some idea of the time, labour, and money which have to be spent in order to bring an important invention to commercial fruition under modern conditions. They also suggest the exceptional type of character that alone can supply the driving force essential to the achievement. Parsons was a prolific inventor because he was gifted with a constructive genius, but he was that rarer thing, an eminently successful one, primarily by reason of the characteristics which Mr. Gibb portrayed.

In considering the history of mechanical engineering, it is surprising to notice how insignificant a part in the production of the most useful inventions can be attributed to mathematical or other academic knowledge. One would not, of course, expect mathematics to be relevant to the invention of such things as the sewing machine, the harvester, the printing press, or of any of the complicated spinning, weaving, bootmaking or other machinery, on the existence of which our material civilisatino so largely depends. But it must also be remembered that steam engines, both stationary and locomotive, were in common use before there was any science of thermodynamics, and when heat was still believed to be an indestructible substance called "caloric" that resided in the pores of bodies. We do not point out these facts with any intention of belittling the value of scientific knowledge. We wish merely to emphasise the truth that a scientific training, as commonly understood, has little more to do with invention than to prevent time and money being wasted on attempts to circumvent the Second Law of Thermodynamics, or to discourage even cruder schemes for obtaining perpetual motion. It will be found to be an almost universal rule that the scientific knowledge bearing on an invention is developed more as a consequence of the invention than as an antecedent to it. The invention comes first in point of time and the mathematics follows after. The only exception to this rule that Mr. Gibb confessed he could think of was the invention of the pivoted-pad thrust block by Michell as the direct outcome of mathematical theory. In the general case the mathematician cannot do much to guide engineers until he has some actual machine or structure to theorise about, and this presupposes its prior invention. Carnot founded the science of thermodynamics by reflecting upon the properties of the steam engine, and not *vice versâ*. Sir Charles Parsons had exceptional mathematical knowledge, having been eleventh wrangler at Cambridge, but he relied rather on intuition, checked by simple arithmetic and practical experiments when developing the steam turbine. The mathematical work which has since been done by others in connection with the thermodynamic and mechanical aspects of the turbine fills innumerable volumes, but the important point is that the turbine existed as an actual machine long before the mathematical theories were elaborated. The function of the latter is to interpret the results and to enable general rules for design to be formulated. Once this state of affairs has been reached in connection with any invention, there comes the turn of some new inventor, who, being bound by no rules but the laws of Nature, strikes out in some new direction; and so the cycle of progress recommences.

Literature.

The Development of Physical Thought. By Leonard B. Loeb and Arthur S. Adams. New York: John Wiley and Sons, Inc. London: Chapman and Hall, Ltd. Price 23s.

It must have occurred to many at some time or another that the finest system of education that could be desired, were there sufficient time for the scheme to be carried out on the youth of each generation, would be one in which the subject was treated in historical sequence. In this way the knowledge of the individual pupil would be made to grow gradually along the same path that had been traced out by the evolution of the thinking processes of the human race. The difficulties with which each pupil would have to contend would then be just those with which the great scientists years ago were wrestling, and each step would follow in orderly sequence from the last. Unfortunately, only an approximation to such a system of education can be adopted owing to the exigencies of time, and the student must by giant strides skip the human, easily understood, errors of earlier generations and be taught at once the scientific facts and theories of the present day. But if on the large scale any such system of education is impracticable we are not prevented in later life from adopting it upon a smaller, less detailed scale with pleasurable, if not necessarily valuable, results.

These reflections were engendered by the enjoyment with which the reviewer read "The Development of Physical Thought," by Leonard B. Loeb and Arthur S. Adams, for in this work the historical method of presentation has been adopted as far as possible, and is thereby demonstrated to be particularly suited to a scientific subject. The number of books published in recent years, and dealing in particular with the modern scientific conception of the universe, bears witness to the widespread interest that is felt in the latest developments. But many of those who have read this more or less popular literature with enjoyment and profit must have felt a desire to penetrate further and to gain a greater insight into the why and wherefore of the various theories. Probably, however, they have been deterred from attempting the more advanced works by a realisation of their own mathematical failings and an uncertainty of the quality of their scientific grounding. What is required is something that is neither "popular" nor "technical," but in this field there has been a distinct gap in scientific literature of recent years. We have no "Huxley" and no "Tyndall" to explain to us in simple language the most advanced principles of the scientists without descending to the purely popular level. The authors of the present work would claim no equality of merit with these famous writers of the last century; nor can it be claimed for them. But at least in a different style, and with less genius for expression, they have produced a book that goes far to fill the literary gap at present existing. Some of the qualities of great writing, too, can be observed in their work. The best lecturers and authors have the quality of imbuing in their students a confidence that, however complex the subject, it is well within their intellectual powers to comprehend it. In reading the present work, one is conscious to some extent of just that confidence, though it is perhaps due to the historical method of treatment and to a certain clarity of description rather than to any genius for choosing the right simile or the simplest analogy. Nevertheless, credit attaches to the authors for choosing a manner of approach which could successfully pass between the Scylla of a collection of pretty qualitative facts and the Charybdis of a mass of formulæ and equations, and which could, without the use of more mathematics than is included in a school course of algebra and geometry, yet give the reader a sound conception of the present position of physical thought.

Naturally enough, in view of its method of construction, the book falls into several parts. For though all sciences may now be regarded as parts of a single "whole," historically they were developed in more or less water-tight compartments. Thus beginning with a part dealing with early history before the scientific experimental methods of the last few centuries were developed, the authors break up their history into its branches, mechanics, heat and the structure of matter, electricity and magnetism, and light in the succeeding pages bringing them together again under the heading "The Electrical Structure of Matter and the New Physics" for the final part. The result is a volume that may be read, not, perhaps, with the ease one associates with a novel, but at least without that mental indigestion which is stimulated by a heavily learned presentation. Almost effortlessly those "tag-ends," the points which, somehow during one's period of training at college or university eluded one's intellectual grasp, are picked up and made clear, and the way is smoothed for the approach to more difficult conceptions. If, in the later pages, matters are not described so clearly, that is not entirely the fault of the authors. Many of the modern conceptions are vague when expressed in any way other than that of mathematics, while others are matters for dispute or discussion among the scientists themselves. In such circumstances only a touch of genius denied to the majority of mortal men can avoid instilling a certain degree of confusion into the mind of the student.

As in many books nowadays, the old system of footnotes giving references to authorities has been dropped in the production of this volume, and the authors have adopted the plan of collecting references to the works of many authors dealing with the conceptions of higher physics on the last few pages before the index. Particularly in such books as this, where references in the text would tend to interrupt the easy flow of the author's discourse, the system adopted is to be recommended.

Practical Acoustics for the Constructor. By C. W. Glover, A.M. Inst. C.E., M.I. Struct. E. London: Chapman and Hall, Ltd. 1933. Price 25s. net.

Although several books of fairly recent origin on the theory and application of acoustics are available, none are so definitely adapted as this new publication to the requirements of the student and practical man interested in the subject of architectural and constructional acoustics. The primary purpose of this treatise, according to the preface, is to set down in a concise form the general principles underlying the applications of acoustical engineering as logically developed from fundamental assumptions. The basis of treatment is largely experimental, and the text is arranged so that it provides a suitable foundation for a progressive course of lectures, and also as an aid for teaching purposes. The subject is discussed in its widest aspects, including the general principles of wave motion, reflection, interference, transmission, and absorption of sound, the acoustical design of buildings, insulation and vibration. The aim throughout has been to treat comprehensively the fundamental principles, so that with thorough assimilation their application to particular problems may present no difficulty.

In certain cases what appear to be original, or little-known methods of attacking the problems, are introduced with advantage. There is an interesting chapter on the effects of reverberation, in which the optima for broadcasting, sound film studios, and gramophone audition rooms is discussed and guidance given for the adjustment of acoustical conditions. Some recorded results are of considerable practical importance, since it is not possible, except by the use of adjustable absorbents, to provide acoustical conditions which will be conveniently satisfactory for the manifold uses to which an auditorium may be put. The section on methods applied for investigating the reflecting characteristics of interiors, deals in an authoritative manner with the photography of sound pulses in a model and the use of the Echo Locator in the building itself.

The author considers that a typical example of faulty acoustical design is that of the Albert Hall, London, being elliptical in plan, with a domical roof, voluminous and reverberant. The correct control of the acoustics of music rooms is very clearly discussed, and its applications to various common arrangements shown. Some typical specification clauses for alternative materials are given as a general guide for the student, but in some cases modifications may be necessary in order to satisfy particular requirements or conditions. The illustrated particulars of numerous acoustical materials, a detailed bibliography, and a summary of acoustical defects are features of the volume which are of outstanding value.

The subject of human susceptibility to noise has received much prominence within recent years, and methods of arriving at remedial measures likely to be most effective in the prevention of vibration and sound transmission are discussed. These include those resulting from ventilating systems, heating installations, water services and lifts. A summary of acoustical coefficients and illustrated particulars of acoustical materials is given in an appendix, and there are numerous uniformly excellent diagrams which, in just a few cases, are not conveniently situated in relation to the corresponding text.

The text gives some indication of the amount of work which has been going on in the sphere of acoustics during the last few years, and one is impressed still more with the amount of patient labour which must have been expended in order to bring the science even to its present position. It must be acknowledged that the development of acoustical science has resulted from, and will rest on, the extension of theoretical work. The reasons why this branch of scientific thought has only comparatively recently been studied with any degree of precision are, first, because of the lack of a theoretical basis, and secondly, because of the experimental difficulties which have had to be overcome. The author does not appear to be at his ease when discussing problems associated with aircraft noise abatement, and the chapter dealing with this subject might with advantage be re-written in the event of a subsequent edition appearing. We would also suggest that statements such as "it would be necessary to have a man speaking continuously day and night for 170 years to generate enough acoustical energy which, when converted into heat, would be sufficient to make one cup of tea" (p. 104) might be left to the popular weekly, and not incorporated in a scientific treatise. The humourous (?) drawings, *e.g.*, p. 61, are not becoming in an otherwise well-prepared volume.

In spite of these observations, which are intended to be constructive rather than critical, it is evident that a great deal of thought and energy have gone towards the completion of a difficult task. Not the least useful feature of the treatise is the inclusion of a number of beautifully reproduced natural-size photographs. Moreover, in order to provide familiarity with the types of problems likely to be encountered, there appears at the end of each chapter a number of exercises for the guidance of the student, and for those who wish to widen their knowledge of the subject.

Road Engineering. By E. L. LEEMING, M.Sc., Assoc. M. Inst. C.E., M. Inst. M. and Cy. E. London: Constable and Co., Ltd. Second edition. 1933. Price 18s.

IN the preface to the first edition of this book, it was described as an attempt to give in a concise form the technology of road construction in the light of the new conditions created by modern traffic. In his preface to the new edition the author further explains that no single volume being adequate to cover the wide field of road engineering, his book is intended to give the general engineering requirements and principles, with the design, plant, and execution of modern works of road construction. Largely in respect of principles, and in regard to many aspects of design, the book fails to satisfy expectations based upon those descriptions of its character.

The work of revising and supplementing the original matter has been well done. Clear explanations are given of methods now generally followed, but seldom, if ever, applied until quite recently. In the chapter on curves, the importance of the transition curve, so long neglected, is made evident, and explanations are given of the employment of the spiral, the parabolic, and Bernouilli's lemniscate curves. The subject of superelevation at bends is handled with good judgment and considerable skill; but the author might have added to his own clear presentment the information that there is a strong body of opinion against a steeper slope than 1 in 12, and that a range of 1 in 12 to 1 in 15 has successfully been adopted by a number of highway engineers.

The author has the courage of his opinions in respect of the slipperiness of asphalt carpets of that class and character the qualities of which were not sufficiently studied before their adoption on a large scale. Discussing the causes of skidding he observes that "the onus would appear to lie with the road engineer rather than with the vehicle designer, as the condition of the road surface in wet weather is primarily responsible for a skid." The first in his list of ten causes of skidding is "smooth, fine road surfaces of bituminous asphalte, having a low coefficient of friction when wet." He remarks, very diplomatically, but unequivocally, that "a considerable mileage of roads with this material has now been constructed in this country, and some treatment is necessary to increase the frictional resistance to wheel traffic. Many of these roads have been laid down at considerable cost and without any thought of annual surface treatment."

References to recent developments in the provision of traffic signals and in measures of traffic control include discussions of the latest systems of controlled and automatic signals.

It is unfortunate that the author, who is a highway engineer of proved ability, and whose judgment, as this book shows, is sound in regard to many aspects of highway engineering, should fail to provide safe guidance in respect of some of the essential principles, basic facts, and important features of design. Apparent in regard to structural features of the roadbed and the carriageway, this failure is most conspicuous in the chapter on subsoils, drainage, and earthworks, which contains only nineteen pages, ten of which are devoted to the qualities of soils. The observations made in the nineteen lines on "curative treatment of subgrades," is definitely misleading as an outline, even, of the main factors to be taken into account in the preparation of the roadbed. The purport of the observations relating to methods of effecting subsoil drainage is, in so far as it can be grasped, unconvincing. The matter under the headings "natural drainage," and "earthworks" occupies only seventy-two lines, the treatment conveying wrong ideas as to the character and importance of the problems and the provisions that should be made to meet various conditions. Mr. Leeming falls into line with those highway engineers who ignore the experience of thousands of years in the control of earth and water, regarding those substances with deep mistrust, and, on the slenderest of pretexts, resorting to the reinforced concrete carriageway.

Since, however, most of the chapters are well written, the subjects adequately discussed, and sound advice given as to methods of construction, it is to be concluded that the book is likely to continue to provide useful guidance for students, while it is a handy work of reference for highway engineers.

Die Statik im Eisenbetonbau. Vol. I. By KURT BEYER. Verlag von Julius Springer, Berlin, W.9, Linkstrasse 23-24. Second edition. 1933. Price R.M. 32·50.

THE title of this work, "The Statics of Reinforced Concrete Construction," seems to have been chosen in order that it might be understood that the author does not attempt to cover the subject as relating, in its closer applications, to structures of other materials. Probably, also, in the second volume —in which there will be a fuller presentment and solution of problems relating to constructions such as continuous beams and girders on elastic supports, continuous frames and other of the more complicated dispositions—the examples will be mainly reinforced concrete structures. As regards the volume under review, the special consideration given, here and there, to reinforced concrete, does not affect its character as indicated in the sub-title (of the whole work) of "A Text-book and Handbook of Structural Statics." Comparable as regards print, illustrations, paper, and binding, with books published by leading English houses, the volume can largely be understood by an engineer conversant with the subject, though his knowledge of the German language be but slight. Employing international symbols and methods, Dr. Ing. Beyer, who is a Professor at the Technical High School, Dresden, makes use of diagrams and tables of familiar forms, largely employing, in tables of functions, constants, and other numerical values, a column of small diagrams indicating the structural form relating to each line of figures. For beams alone eight pages of such matter and a large folding plate are furnished.

The large pages, 9½in. by 6¼in., allow of very clear presentment of tabular matter and graphs, and though the reference numbers, each relating to a line, or a series of lines, of mathematical expression, total more than 630 and the figures number about 350, the book is well supplied with studies of the groundwork of the subject and with explanations and discussions of problems and of the methods of their solution. The author's treatment and solutions of retaining wall problems are on familiar lines, but in a table on page 12 of five functions for massive retaining walls, these are given for eleven kinds of earth or ground material, and, in respect of six of those materials, the value of "gamma" is given for the conditions—dry, naturally moist, and saturated. In an exposition of the solution of the statics of a silo, results are given, separately for wheat and rye, for internal, or load, heights up to 21 m., while another table (page 14) gives the four physical constants for six mineral or similar materials, including coal and cement, for five cereals, and for beans, peas, linseed, malt, and salt.

Influence lines are discussed, the method of explaining strain problems with the aid of distorted figures is usefully employed, and considerable attention is given to the solution of problems such as are presented by frame structures having north-light or other unsymmetrical roofs, to take only a few examples which may serve to suggest the thoroughness of the treatment of the subject.

Dr. Kurt Beyer's lucid exposition may be regarded as usefully supplementing the information contained in British and American works on structural statics.

SHORT NOTICES.

Automotive Engines. By P. M. Heldt. Nyack, N.Y. P. M. Heldt. 1933. Iliffe and Sons, Ltd., London, agents. Price 32s. 6d.—This edition is the eighth through which this book has passed, a sufficient tribute to the fact that automotive engineers have found it of value. Much new material has been added and alterations have been found necessary in chapters devoted to particular parts. A complete new chapter on Torsional Vibration and Vibration Dampers has been added and presents a comparatively simple method for predetermining the critical speeds of torsional vibration. In addition, the chapter on the Determination of Bearing Loads has been completely re-written. Some idea of the amount of revision rendered necessary by the continued rapid advance in engine design may be gained from the fact that more than 100 new illustrations are included in the present volume. In order to make it possible to issue the book at a price lower than that of the previous edition, the decision was made slightly to narrow its scope. Consequently, the chapters on Diesel-type Automotive Engines, Two-stroke Cycle Engines, and Sleeve-valve Engines, have been left out. As to the omission of the first, there can be little doubt that it was a wise move, since the development of this form of engine has now reached the stage where its discussion can fill a whole volume. As to the others, the importance of these types appears to be on the wane, and if anything had to be left out it was better that it should be these chapters than that the very full treatment of the rest should suffer curtailment. The book is, of course, an American one, and deals most particularly with American practice. Nevertheless, the general theoretical and fundamental principles of automobile engine design are necessarily the same on each side of the Atlantic, while the practice is not so far different that that of the one country can learn nothing from that of the other.

Technique of Modern Welding. By Professor P. Bardtke. Translated from the second edition by Harold Kennedy. London: Blackie and Son, Ltd. 1933. Price 15s.—This book was first published in Germany four years ago, but since that date development in welding practice and in the knowledge of the processes involved has been so rapid that it was necessary to make a very thorough revision. Consequently, even in Germany the book may be regarded as practically a new one, while in our English translation it is quite new to this country. Indeed, as the translator has revised certain sections of the German second edition, and brought them into line with the most recent developments, it might almost be said that the English translation is of greater value than the original German. The book is divided into three parts—Welding Processes; Applications and Tests of Welded Joints; and Gas Cutting. In the first part, after an introductory chapter on the history of the subject and the definitions of the various technical terms, fusion welding, pressure welding, and aluminium thermit welding are discussed. The equipment necessary, its installation, the preparation of the material, and the actual process as applied to various metals are described. In the second section the application of welding technology to various jobs is described, and a discussion of the stresses welded joints may be expected to stand and methods of carrying out tests is presented. A chapter on accident prevention also finds a place in this section. Part III. —Gas Cutting—as might be expected, is the shortest, occupying only 18 pages out of a total of 299.

Modern English Punctuation. By Reginald Skelton. London: Isaac Pitman and Sons, Ltd. 1933. Price 2s. 6d.—Why anyone should want a manual on Punctuation, and how "modern" punctuation can differ from ancient punctuation, we find it hard to understand. Possibly it arises from the ever-increasing desire to do everything according to rule and to remove all trace of those little inconsistences which add a spice to literature. There is but one sound rule for punctuation, and none other matters. Use the stops so that you may increase the clarity of your expressions, and do not use them to excess. We are glad to observe that Mr. Skelton displays a good deal of common sense in making his recommendations, and with some of them which are opposed to common practice we are in full agreement. With others we do not agree. As we say, we find it hard to understand why people get confused over punctuation, but as there are such people, this book may serve a useful purpose, if it does not blind writers to the simple rule which we have enunciated. If everyone was taught, as young people used to be taught, to read aloud, punctuation would lose its terrors.

The Mechanical Transmission of Power. By the late G. F. Charnock. London: Crosby Lockwood, Ltd. 1933. Price 8s. 6d.—This little book of 148 pages is particularly concerned with the transmission of power to line shafting, but since the general principles are the same in any form of mechanical transmission, this limitation is not in the least disadvantageous. In the introductory chapter, the importance of making allowance in the design of a factory building for the forces brought into play by line shafting is stressed, and the various methods of power transmission are classified. The remaining chapters, all of which are profusely illustrated, principally by scale drawings, are concerned with Bearings for Line Shafting; Belt Driving; Types of Pulleys; Rope Driving; Chain Driving; Toothed Gearing, including Some Description of Methods of Producing Gears; Friction Clutches for Power Transmission; and, finally, Variable-speed Transmissions. Although not unduly obtruded, the mathematical side is not neglected. Much use is made of graphs and other similar explanatory diagrams.

Automobile Electrical Equipment. By A. P. Young and L. Griffiths. London: Iliffe and Sons, Ltd. 1933. Price 15s.—In this book a subject of great importance to the automobile industry and to the aircraft engine designer is studied. Ever since motor cars were first produced the use of electricity, not only for ignition purposes, but also for the operation of auxiliaries, such as the lights, horn, and windscreen wiper, speedometer, petrol gauge, &c., has been increasing. So much, in fact, is this the case that the authors have found plenty of material to fill a book of 330 pages. As might, indeed, be expected from its relative importance, the subject of ignition takes up a very large proportion of the book, which, besides describing various types of magnetos, sparking plugs, coils, distributors, &c., also discusses the principles underlying the design of such components. Other important sections are concerned with batteries, the starting motor, and the dynamo or generator. The subject of lighting is not neglected, and the dazzle problem is discussed and several anti-dazzle devices described.

The Elements of Reinforced Concrete Design. By H. C. Adams. London: Concrete Publications, Ltd., 20, Dartmouth-street, S.W.1. Price 6s. net.—This textbook is intended to be a complete course for the student of reinforced concrete design. It contains a full discussion of the statics of structures and shows by worked examples how any concrete structure is supported. Examples are given of designs for simply supported and continuous slabs and beams, columns and footings, thus providing all the necessary details for designing a structure. The author explains the action of earth pressure on retaining walls and gives complete designs of cantilever and counterpart walls. The book is written in simple language and uses only the most elementary mathematics, and the information it contains is based upon the practice of British firms specialising in reinforced concrete construction.

Radio Upkeep and Repairs for Amateurs: A Practical Handbook in Fault-clearing and Set Maintenance. By Alfred T. Witts, A.M.I.E.E. London: Sir Isaac Pitman and Sons, Ltd. 1933. Price 5s.—Of the millions of users of wireless there is certainly a very large number who like "fooling about with the radio," as Stevenson liked "fooling about with boats." To them, if they are not already adepts, this little book will be a godsend, and if they are adepts they will enjoy it, for we all like reading about our hobbies. It is an excellent guide to fault-finding, but its title hardly does it full justice, for it carries the reader beyond maintenance into actual improvements and additions. We commend it as a suitable Christmas gift for the embryo radio-fan.

Standard Methods of Analysis. Sheffield: The United Steel Companies, Ltd., 17, Westbourne-road. Price 4s. 6d. net.—This little volume is the product of a committee of chemists and metallurgists from the various laboratories of the United Steel Companies' works. It contains the selected standard methods of analysis of iron, steel, and ferro-alloys now employed in the manufacture of the companies' output, and no short or approximate methods are given. There is no doubt that this book will be read with much interest by all connected with the iron and steel industry.

A.C. Voltage Regulators.

No. IV.

(*Continued from page 566, December 8th.*)

ALTHOUGH the Cowan-Still induction regulator made in modern form by Switchgear and Cowans, Ltd., of Old Trafford, Manchester, was invented as far back as 1895–6, other types of regulators of more recent origin have by no means rendered it obsolete. Well known as the principle of operation is, it is, perhaps, advisable to explain that the variation of mutual inductance between two sets of windings, brought about by a change of position of one with respect to the other, gives the pressure regulation desired. The primary or shunt winding A, Fig. 33, is connected across the supply circuit, the secondary B being in series with the circuit to be controlled. Usually, the primary is mounted on the movable core, while the secondary is stationary. Voltage variation is obtained by altering the angular position of the former relative to the latter. The alternating magnetic flux produced by the winding A induces a pressure in the secondary B, which varies in magnitude with the angular position of the rotor.

Fig. 33—Single-Phase Induction Regulator

In a single-phase regulator, such as that shown in Fig. 33, voltage variation from full boost to full buck is effected by turning the rotor through 180 deg., which can be done when necessary on an automatic motor-operated Switchgear and Cowans regulator in a period of seven seconds, or even less, with the use of a special relay. The electromotive forces produced in the stator by this rotary motion are, of course, quite negligible in magnitude as compared with the maximum electromotive force due to flux alternation. The object of the short-circuited compensating winding C is to limit the leakage reactance of the stator winding, which would otherwise reach a prohibitive value as the rotor approached the mid or neutral position. It is claimed that in the latest single-phase regulators made by Switchgear and Cowans, an unequalled uniformity of leakage reactance is attained without the introduction of large magnetising currents, a matter of particular importance in the case of a low power factor. As the rotor and stator slots are proportioned so that the air gap reluctance is uniform throughout the range, it follows that the magnetising current is also uniform and that the rotor is not subjected to a uni-directional torque pulsating at twice the frequency of the supply and consequent vibration.

Fig. 34—Single-Phase Gulator Vector Diagram

The approximate relations existing between the pressures and currents on the supply and load sides of a single-phase regulator capable of giving 20 per cent. boost and an equal buck, are shown vectorially in Fig. 34. The regulator is assumed to be in the full boost position, with the line fully loaded and with a lagging power factor of cos φ_2 on the load side. At full load the internal reactance drop is taken as approximately 20 per cent. of the voltage boost, or 4 per cent. of the supply voltage O V_1. Similarly, the magnetising current is assumed to be 20 per cent. of the shunt winding full ratio current, *i.e.*, 4 per cent. of the full load current O I_2. As the vector diagram shows, the effect of these internal characteristics on the power factor of the line is small, particularly as the boost and buck required are most frequently 10 per cent. and less. Under full load conditions, the maximum difference between φ_1 and φ_2 at unity power factor in the case of a regulator for 10 per cent. boost and buck with a 20 per cent. magnetising current, and 20 per cent. internal reactance, approximates 2·3 deg.

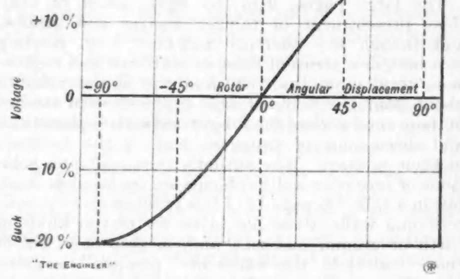

Fig. 35—Induction Regulator Characteristic Curve

From the operating point of view, the relationship between the booster voltage induced in the series winding and the rotor position is important, for the sensitivity with given control gear depends on the nature of this relationship. A characteristic curve is given in Fig. 35 of voltage boost plotted against rotor angular displacement for a Switchgear and Cowans single-phase induction regulator working under no load conditions, while Fig. 36 shows the leakage impedance plotted against rotor angular displacement and indicates the satisfactory form of the voltage boost angular displacement curve for any loading condition. It also shows the variation in copper loss with full load current in the series winding for the entire range, and it will be observed that the copper losses are lowest in the neutral position.

VECTOR DIAGRAM FOR THREE-PHASE REGULATOR UNIT 20% BOOST AND BUCK.
Swain Sc.

Fig. 37—Three-Phase Induction Regulator Connections

Three-phase Induction Regulators.

A diagrammatic representation of the windings of the most common form of three-phase induction regulator is given in Fig. 37. O A_1, O B_1, and O C_1 are the star-connected shunt windings carried by the rotor, and A_1 A_2, B_1 B_2, C_1 C_2 are the corresponding series windings housed in the stator. By altering the angular position of the rotor, and thereby causing a phase shift variation in the line pressure is produced without an alteration of the magnitude of the voltages in the series windings. The angle θ represents the displacement of the rotor from the maximum boost position, *i.e.*, that in which the axes of corresponding shunt and series windings coincide, the direction of the rotating field being assumed to be clockwise. In Fig. 37 the line to neutral vector diagram shows the pressure and current relationships corresponding to the position of the rotor, and relates to a Switchgear and Cowans regulator capable of giving a buck or boost of 20 per cent. As internal resistance and leakage reactance voltage drops are of as little importance as they are in a case of a single-phase regulator, they are not included, but the vector of magnetising current i_M is shown for the purpose of indicating its relationship with the rotor current I_R in the shunt windings.

Movement of the rotor from the maximum boost position to the full buck position involving rotation through 180 electrical degrees, may be made in a clockwise or anti-clockwise direction, but when the phase rotation is clockwise an anti-clockwise movement is preferable from the point of view of copper losses in the shunt winding. If the rotor is turned in the unfavourable direction i_R in its angular movement with respect to O I_2 eventually coincides in phase with i_M. The difference between the power factor on the supply and load sides of the regulator is caused by the magnetising current and the internal leakage impedance drop, which is not shown in the vector diagram, Fig. 37. The phase difference θ between the supply voltage O A_1 and the series winding boost A_1 A_2, introduces an equal phase shift in line voltage and current which is not objectionable when the system on one side of the regulator is only connected to the system on the other side through the regulator and in no other way.

Twin Induction Regulators.

By the use of two regulators, however, as shown in Fig. 38, the phase difference between the voltages on the two sides of the regulator may be obviated. Each regulator has half the required total capacity, and the voltage phase shift of one is in the opposite sense to that of the other. As the boost windings of the two regulators are in series and have the same induced voltages, their resultant effect is to give a voltage boost in phase with the line voltage, as shown in Fig. 38. Alternatively, the phase difference may be overcome by installing a polyphase bank of single-phase units, which, in some cases, is cheaper.

Induction Regulator Construction.

The general construction of induction regulators resembles, as most engineers know, that of wound rotor induction motors. Individual manufacturers may naturally claim special points, but, broadly speaking, all these regulators consist of a laminated stator core with windings and a rotor composed of a wound laminated core mounted on a shaft. Generally, they are oil-immersed in welded boiler plate tanks. The stresses imposed on the insulation depends on the severity of line surges prevalent. Switchgear and Cowans regulators are designed to withstand short circuits up to a maximum of twenty times the full load current for two seconds, or even more severe short circuit conditions if necessary.

All regulators of this kind may be hand, remote or automatically controlled. Hand control is fitted on all regulators made by the above firm, and serves in the cases of remote and automatic-controlled equipments as a standby. When a regulator is intended for hand control alone, a hand wheel is fitted either direct to the worm gearing shaft on the top plate, or through suitable shafts, bevels, and pinions in the case of remote mechanical control. The rotor of a remote electrically controlled regulator is moved by means of motor controlled by hand from a switchboard, or by conveniently situated push-buttons, the motor being arranged to drive the shaft through gearing. Under full load conditions the maximum torque possible is equal to that of an induction motor of the same kVA and number of poles. In a single-phase regulator a resultant pulsating torque exists when the power factor is less than unity, and when the regulator is not in either of its extreme positions. It is, therefore, necessary to make the operating gear self-locking, which is done by the use of worm gearing with a worm thread angle not exceeding 4 deg. On motor-operated regulators provided with this gear, convenient speed reductions, such as 1000 to 1, are readily obtained. Over-travel of the rotor of motor-operated regulators due to inertia can be prevented when necessary by a magnetic brake. Limit switches and mechanical stops prevent the rotor moving beyond its range, which, in the case of a two-pole regulator, is 180 deg.

Fig. 38—Twin Three-Phase Induction Regulator Connections

Automatic Control.

Induction regulators may readily be automatically controlled by means of relays. The modern Switchgear and Cowans relay is fitted with two pairs of sparkless contacts, which are normally open. Intermediate contactors are interposed between the voltage and the main motor operating contactors, the coils of the smaller contactors being shunted by a condenser so as to reduce the duty of the voltage relay contacts. In the case of simple feeder control the function of the automatic voltage relay is to close the operating motor circuit when the voltage deviates by 1 per cent. or more from the correct value. On ring mains the relay may be required to operate when a difference occurs between two voltages, and the beam of the regulator is then controlled by two opposing forces produced differentially, phase differences having no effect.

Line Drop Compensators.

By passing a current in phase and proportional to the line current through an impedance a voltage drop is obtained corresponding to the line voltage drop, the impedance being adjusted to correspond with the line constants. Such an arrangement is known as a line drop compensator, but it does not apply to circuits in which considerable loads are taken from the feeder between the regulator and remote points at which voltage regulation is required. The diagram, Fig. 39, shows a three-phase regulated line with an automatically controlled induction regulator. With equilateral triangular spacing of three-phase conductors the reactance drop for any two conductors is solely determined by the currents in these conductors. Thus if, as shown in Fig. 39, two current transformers with their primaries in two phases of the system and with their secondaries cross connected feed a line drop compensator, a voltage drop in phase with and proportional to the voltage drop between the two phase conductors is obtained. But, when the spacing of the three-phase conductors is not symmetrical, the line drop compensator supply system will necessarily be more intricate. Adjustment of the apparatus for line capacity may be made, when necessary, by means of the potential transformer P.T.

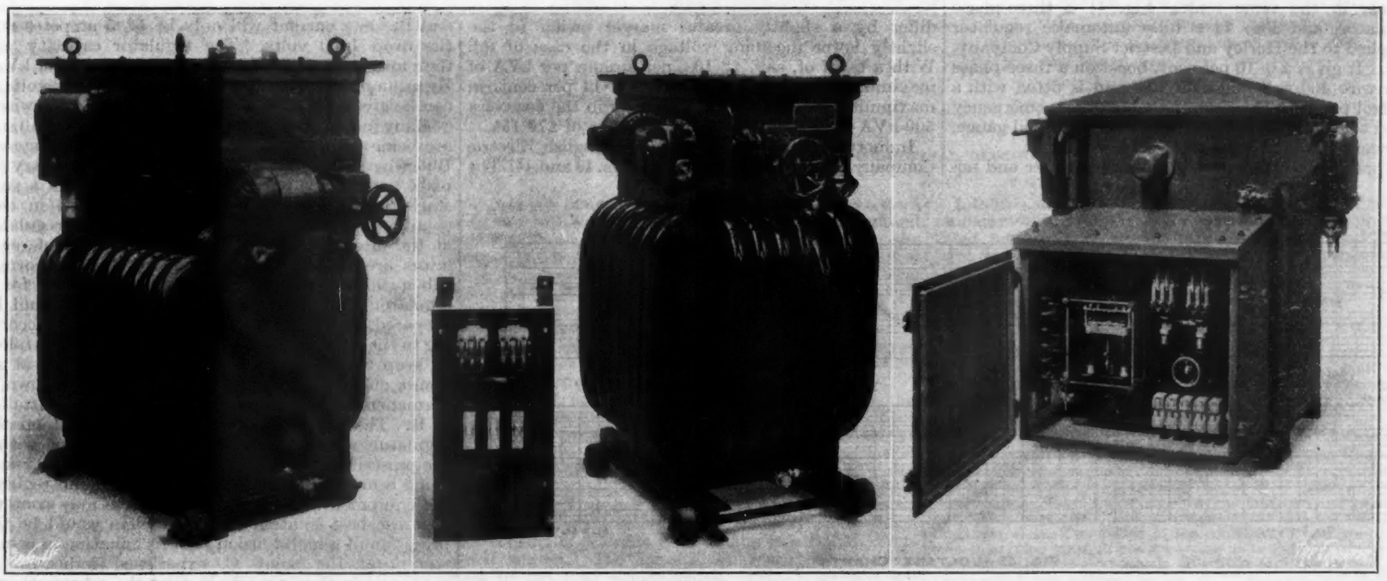
Fig. 39—Automatically-Controlled Three-Phase Induction Regulator

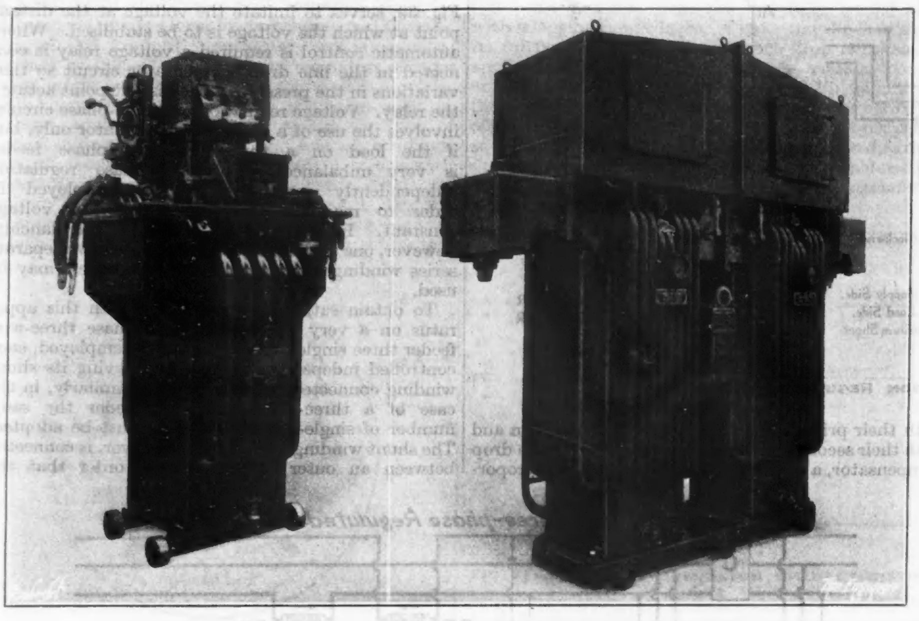
The Application of Induction Regulators.

On a dead end feeder the induction regulator is introduced to compensate for fluctuations of pressure on the supply side and also for the drop in the feeder produced by load current, and it may be installed at any convenient point. A line drop compensator used in conjunction with a potential transformer connected on the load side of the regulator, as shown in Fig. 39, serves to imitate the voltage at the distant point at which the voltage is to be stabilised. Where automatic control is required a voltage relay is connected in the line drop compensator circuit so that variations in the pressure at the distant point actuate the relay. Voltage regulation on single-phase circuits involves the use of a single-phase regulator only, but if the load on a three-wire single-phase feeder is very unbalanced two single-phase regulators independently controlled may be employed in order to maintain the line to neutral voltage constant. In the absence of serious unbalancing, however, one single-phase regulator with two separate series windings connected in the two outers may be used.

To obtain satisfactory regulation with this apparatus on a very unbalanced three-phase three-wire feeder three single-phase units can be employed, each controlled independently and each having its shunt winding connected between lines. Similarly, in the case of a three-phase four-wire feeder the same number of single-phase regulators must be adopted. The shunt winding of each unit, however, is connected between an outer and neutral in order that the voltages between these conductors may be maintained constant for any load condition within the limits of the regulator range. Sufficiently close voltage regulation on three-wire single-phase and four-wire three-phase systems may, however, be obtained by a single regulator and a static balancer connected at a point as close as possible to the



Figs. 40 to 42—Switchgear and Cowans Induction Regulators unbalanced load. When serious unbalancing does not occur on a three-phase feeder the three-phase unit is applicable as an alternative to three single-phase units, and in the case of a three-phase four-wire feeder it is necessary to connect the star point of a star-connected three-phase unit or a three-phase regulator bank to the fourth wire of the feeder in order to provide a path for any out-of-balance current in the regulator windings. The three-phase regulator is cheaper than a bank of regulators, but the three-phase bank offers the advantage that the maximum potential difference normally existing in any one unit working on a system with earthed neutral and with the regulator shunt windings star connected is the line to neutral voltage.



FIGS. 43 AND 44—ENGLISH ELECTRIC INDUCTION REGULATORS

In the voltage regulation of all types of feeders and lines generally, static auto-transformers are often used to supplement induction regulators, as the latter are inherently capable of a positive and negative boost. Hence, in cases where, for example, a positive boost only is required, say from 0 to 10 per cent., the most economical regulating equipment consists of an induction regulator for plus 5 per cent. to minus 5 per cent. boost, and a static auto-transformer for plus 5 per cent. boost.

Although electric generators are now made to work at 36 kV, the maximum voltage for induction regulators appears at present to be about 14,000 volts. Circuits working at higher pressures, therefore, call for a step-down transformer to supply the shunt windings and a series transformer to reconnect the line, the capacity of each being approximately equal to that of the regulator. On lower voltage circuits on which the ratio of voltage to internal kVA is too large to make a directly connected regulator economical, transformers may also be required. Examples of Switchgear and Cowans automatic induction regulators are illustrated in Figs. 40 to 42. The first shows a single-phase regulator with an auto-transformer in the same tank; Fig. 41 a three-phase regulator, and Fig. 42 a fully automatic regulator supplied to the Horley and District Supply Company, Ltd. It gives a 0–10 per cent. boost on a three-phase four-wire 400-volt 100-kVA line and is fitted with a control panel on the side of the tank, an emergency hand wheel, oil filling valve, oil drain valve, oil gauge, thermometer, and removable cable boxes.

Apart from tap-changing gear, the copper and no-load losses, magnetising kVA and leakage reactance are claimed to be smaller on these regulators than on any other type. Large magnetising kVA and leakage reactance will lower the line power factor and thereby give rise to increased line copper losses and increased maximum kVA demands. For the sake of illustration the makers of these regulators make a comparison of (*a*) an induction regulator, and (*b*) a regulator of no particular make having an extremely large magnetising kVA and reactance, both designed for a boost of ±10 per cent. The magnetising current for (*a*) is 3 per cent. and for (*b*) 10 per cent. of the line kVA. The average value of leakage reactance voltage for the whole regulator range for (*a*) is 2 per cent. and for (*b*) 7·5 per cent. of the line voltage. Copper and no-load losses are assumed to be 0·5 per cent. and 0·2 per cent. of the line kVA for both (*a*) and (*b*).

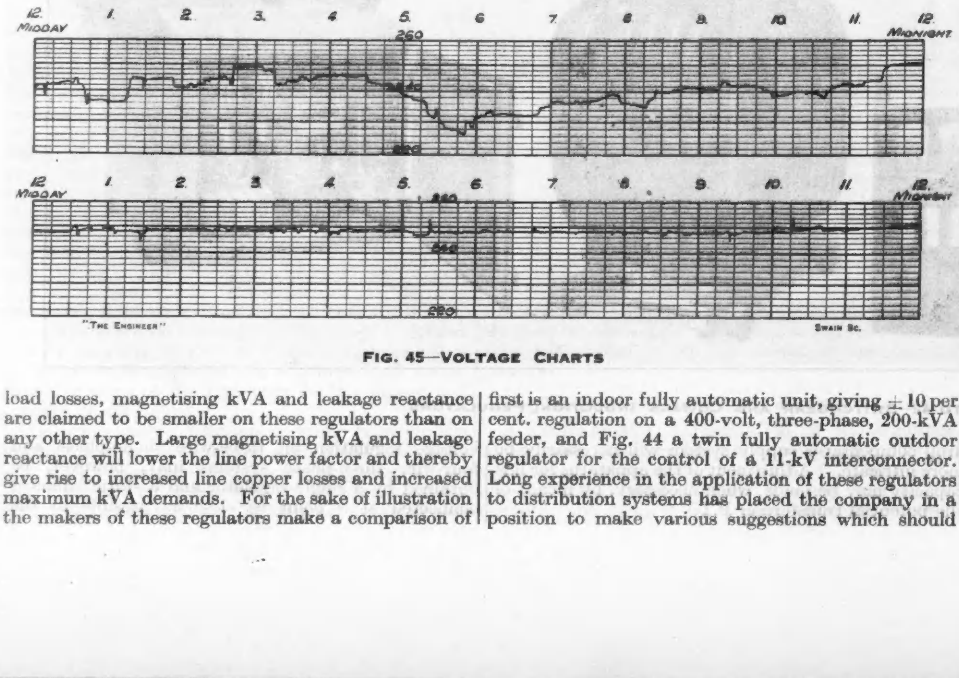


FIG. 45—VOLTAGE CHARTS

It is shown that the incoming power factor values corresponding to full load and 0·9 lagging on the outgoing side are 0·881 and 0·830 for (*a*) and (*b*) respectively. Hence the incoming kVA in the case of (*b*) is $\frac{0\cdot881}{0\cdot830}$ times that for (*a*), or 6·14 per cent. more, while the line currents on the supply side would differ by a slightly greater margin owing to the slightly lower incoming voltage in the case of (*b*). With a tariff of, say, £2 10s. per annum per kVA of maximum demand a difference of 6·14 per cent. in maximum kVA demand would mean in the case of a 500-kVA feeder an extra annual charge of £76 15s.

FIG. 46—SINGLE-PHASE 3-WIRE DISTRIBUTOR VOLTAGE DIAGRAM

Induction regulators made by the English Electric Company, of Stafford, are shown in Figs. 43 and 44. The first is an indoor fully automatic unit, giving ±10 per cent. regulation on a 400-volt, three-phase, 200-kVA feeder, and Fig. 44 a twin fully automatic outdoor regulator for the control of a 11-kV interconnector. Long experience in the application of these regulators to distribution systems has placed the company in a position to make various suggestions which should appeal to distribution engineers. Unsatisfactory voltage regulation at consumers' terminals may, as explained at the outset, be due to one or a combination of three main causes, *i.e.* (1) bulk supply variations; (2) distribution drop, including transformer regulation; and (3) out-of-balance loading. In many cases bulk supply variation is inevitable, and the rules which allow a greater voltage variation on the bulk supply than can be passed on to the consumers are well founded. A large supply system may be connected directly to the grid. From the bus-bars of the undertaking supplies may be given to smaller undertakings several miles away at 6·6 kV or 11 kV. As the bus-bar voltage is controlled to suit the main supply, the smaller undertakings are naturally subjected to variations which must not be passed on to consumers. If there is diversity between the respective peak loads the conditions are aggravated. Frequently there are three or more transformers between the point of controlled voltage and domestic consumers, each contributing together with distribution drops to an unsatisfactory state of affairs.

On distribution systems cookers and radiators connected between phase and neutral have a serious unbalancing effect. Added to this is the almost universal experience that the heaviest cooker and radiator load is at the extreme end of the distributor, thus causing the maximum neutral conductor drop. All of these items have probably contributed to the unsatisfactory conditions indicated in the upper voltage chart shown in Fig. 45, which is a voltage curve taken under actual practical conditions. The lower record, Fig. 45, shows the effect of installing a regulator.

POSITION OF REGULATOR.

When small undertakings receive a bulk supply from a larger undertaking without tee connections, the outgoing panels on the bulk supply switchboard are usually separated from the local feeder panels by a metering panel, so that the bulk supply for the distant area, which may be several miles away, is metered at the sending end. In the majority of such cases it is most economical to arrange for the regulator at the sending end, particularly if for the most part the voltage variation is due to drop on the interconnector feeder. Assuming that it is required to receive 1000 kVA at 11,000 volts, 52 ampères, and that for this load the line has a drop of 1760 volts, before regulation the received load will be at 9240 volts, 64 ampères. The induction regulator must therefore be built for ±880 volts, 64 ampères, or 97·7 kVA. But if the regulator is at the sending end the line current will only be 52·5 ampères and the drop 1400 volts. The regulator capacity will therefore be ±720 volts, 52·5 ampères, or 66 kVA. By means of line drop compensation a constant voltage can be given at the receiving end without pilot wires.

Many induction regulators of medium and small size are being employed on 400/230 distribution systems. But whereas in America it has been customary to place a regulator on each outgoing line from a sub-station containing a battery of regulators, in this country there is a tendency to place the regulator at the most effective point. The majority of regulators are therefore independent of the transformer sub-station. To determine the best position for a regulator a line voltage diagram, Fig. 46, should be prepared, giving the drops along each section, according to the load distribution, to enable steps to be taken to keep the voltage within the desired limits at all points on the distributor. In the example shown, a permanent step auto-transformer has been installed at B. This permits of both buck and boost on the regulator, and helps to keep the line voltage within the prescribed limits throughout its length, the result being a more economical use of the line and regulating equipment. While some engineers may contend that the best solution of the problem would be the provision of a high-tension line, terminating in a sub-station at the point C, experience indicates, as explained in the first article, that the scheme shown in Fig. 46 is often preferable. Even if the additional initial cost of the high-tension line appears to be justified by possible future developments, it has repeatedly been found that regulating gear has postponed the necessary new sub-stations for several years. The cost involved has not been more than a few years' interest on the ultimate capital outlay.

In the meantime the direction of load development can be studied and definite plans may be made for the future. When load development demands a sub-station, the regulator may be moved to another spot.

In some cases the capacity of a distributor is increased and the supply extended by terminating the existing conductors at a new distribution pillar, and by connecting a regulated feeder in parallel with the distributor, as shown in Fig. 47. Equal voltage is maintained at both ends of the feeder, so that the existing conductors draw energy in both directions, and the capacity is virtually doubled. A new distribution centre is also created. A twin induction regulator will, of course, be required as phase shift is not permissible. Regulator devices having a large reactive component must also be avoided on account of circulating current.

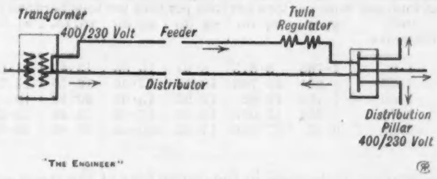

FIG. 47—REGULATED FEEDER IN PARALLEL WITH DISTRIBUTOR

In cities and towns in which sub-station sites are very costly and often difficult to obtain, saving in capital may become possible by adopting the scheme shown in Fig. 48. A large sub-station at A is equipped with transformers and regulators. From this sub-station feeders radiate to centres X, Y and Z, and line drop compensation is provided to give constant voltage at these points, irrespective of the load. The feeder cables can be run at their maximum economic loading, as voltage drop does not enter into consideration. Compared with the cost of two or three sub-stations erected on expensive sites, the single sub-station and its equipment, illustrated in Fig. 48, shows marked financial advantage. Service is also improved, as correction is made for high-tension variation and transformer regulation.

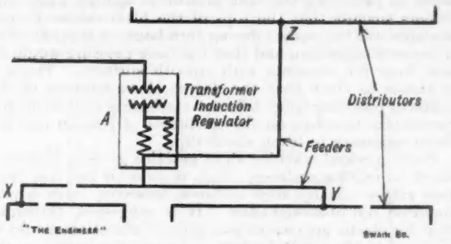

FIG. 48—INDUCTION REGULATOR IN SUB-STATION

LOSS DUE TO LOW VOLTAGE.

The importance of good regulation is well exemplified by a case cited by the English Electric Company. In a certain district a large number of cookers were returned because they were unsatisfactory, whereas in neighbouring districts deriving current from the same source they were highly praised. Bad voltage regulation proved to be the cause of the complaints, but the installation of induction regulators eventually led to the re-installation of the cookers, which are now giving entire satisfaction.

The loss of revenue to supply undertakings when the voltage is low was mentioned in the first article, where it was stated that the watt consumption of lamps may be taken as a reduction of 1·5 per cent. for each 1 per cent. reduction in voltage, and that of heating appliances 2 per cent. under the same conditions. Assuming a 100-kVA load, with an overall load factor of 28 per cent., made up of one-third lighting, one-third heating, and one-third of appliances such as water heaters, in which the consumption is not affected by voltage variations, a drop in voltage of 10 per cent. will have the following result :—

Units per annum at normal voltage	246,000	
Lighting units p.a. at 10 per cent. reduced voltage		69,700
Heating units p.a. at 10 per cent. reduced voltage		65,600
Unaffected units p.a. at 10 per cent. reduced voltage		82,000
	217,300	217,300
Lost revenue for	28,700	

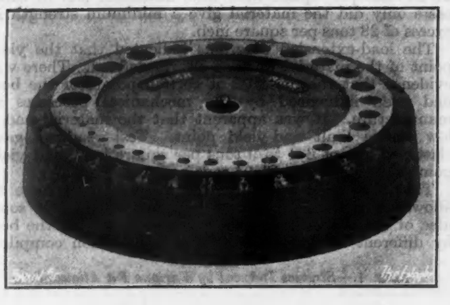
If it be assumed that the whole of these lost units are on a fixed charge of 0·75d., and the unit charge to the supply authorities is 0·30d., there will be 28,700 units at 0·45d.=£53 16s. lost revenue. Although these calculations are on a very conservative basis, they serve to show that the necessary regulator would pay its capital cost in less than two years.

(To be continued.)

ACCORDING to the latest information, it is expected that new telephone cables between India and Ceylon will be laid by March next year.

A Die-cast Drill Stand.

THE accompanying block illustrates clearly a neat bit of die-casting in a white metal done by Fry's (London), Ltd., 24/25, King-street, E.1. As will be seen it is a drill stand, and owing to the absence of machining can be retailed at a low price. It is painted green with the drill sizes raised and gilded, so that they are easily distinguished. The holes range from ⅛in. up to ½in., rising by 64ths, and we have found that standard drills are a comfortable fit. The casting is, we need hardly say, hollow below, but is provided with a local protrusion to accommodate the drill holes. The diameter is 6in.



FRY'S DRILL STAND

Gaseous Discharge Lighting at Ilford.

THE recently completed installation of Mazda Mercra lighting in Romford-road, Ilford, marks another step in the progress of gaseous discharge lamps. Most of the previous installations of the kind have been on arterial roads, where the colour of the light is not an important factor, but the Ilford installation is said to afford evidence that the new system of illumination is also satisfactory in urban districts. The stretch of the Romford-road on which the lamps have been installed is about ¼ mile long, and the open space at Seven Kings Station has been similarly equipped. Owing to the great width of the road and the disposition of the tramway standards carrying the lamps considerable difficulty was previously experienced in providing satisfactory illumination in the area outside the station. The use of Mazda Mercra lamps in B.T.H. circular lanterns giving a wide dispersion of light has, however, solved the problem. Adequate illumination over the whole area is said to have been obtained without changing the position of the units, although much better results could have been secured if this had been possible.

The B.T.H. circular lanterns used for illuminating this particular area have been designed for illuminating open spaces, such as railway yards, docks, car parks, &c., on which a good spread of well-diffused illumination is required. Essentially the fitting consists of an over-reflector and a cylindrical opal glass suitably ventilated.

On the Romford-road section of the installation thirteen lighting units are attached to the tramway posts. Each unit consists of a Mazda Mercra lamp in a B.T.H. directional lantern. The lanterns are spaced on alternate sides of the road approximately 120ft. apart and are mounted at a height of 20ft. According to the kind of light distribution required the B.T.H. directional lanterns are made in several patterns, and the type used in the Romford-road installation is designed to give equal illumination up and down the road, but a greater intensity across the road than on the pavement.

Notwithstanding the low mounting height of the lanterns, the illumination on the road surface is said to be remarkably uniform and there is an entire absence of the patchiness frequently associated with the use of large units. A series of foot-candle tests has been taken between posts and it has been found that, in spite of the fact that the mounting of the units is much too low for units of the size employed, the uniformity of illumination is remarkably good.

The Industrial Machine.

By D. DIXON.

THE accompanying diagram of the industrial machine illustrates the causes of the trade depression and the immediate needs of industry.

The total costs of industry in the form of wages, salaries and profits, payments for raw materials which become wages, salaries and profits, together with rents, interest and reserve charges, equal the price of the total product. Those costs must be distributed as purchasing power to provide the demand for the product, and the purchasing power must be used and exhausted if the demand is to be adequate and production is to continue.

Furthermore, it must be suitably proportioned between investment purchase and consumption purchase. Excessive saving for investment purchase from large incomes, or from small incomes to provide old age security, means too great a demand for investment products, which cannot, however, be bought profitably and used for continued and profitable production as the consumption demand is inadequate. The machine therefore becomes congested and slows. A stronger pull on the consumption channel from wages and salaries is necessary and a weaker pull from investment buying on the investment goods channel.

Moreover, the investment demand can be maintained less from unearned rents, debt interest and high profits and more from the channel fed from reserve charges.

The continuous increase in reserve charges to provide for future increased machine power means also a continuous lag in the necessary total of investment and consumption purchasing power. The extent to which reservation for new equipment exceeds expenditure on equipment must be offset by new money from central banking organisations, with price level of a range of basic commodities as a valve for the amount. It is thus an increase of money concurrent with increase of total wealth to prevent deflation and keep prices reasonably stable.

Improved trade depends on a substantial and general lift in the standard of living and a managed money system independent of gold.

THE INDUSTRIAL MACHINE

International trade does not affect principle, as it is fundamentally an exchange of goods for goods—complicated by export of surplus investment goods and the import of income in the form of goods from investments and services.

LAUNCHES AND TRIAL TRIPS.

CELERITY, steel coal barge, 130 tons displacement; built by Richard Dunston, Ltd., to the order of Yorkshire owners; launch, December 2nd.

ASSOCIATION OF CONSULTING ENGINEERS.—The annual dinner of the Association of Consulting Engineers (Incorporated) was held on Thursday, December 7th, at St. Stephen's Club, Westminster. There was a large party of members and guests, numbering over 180. The chairman was Mr. A. M. Sellar, Chairman of the Committee of the Association, who presided over an evening which in every way was up to the high standard the Association has established. The toast of "The Houses of Parliament" was proposed by Mr. W. T. Halcrow, and replies were made by Lord Meston and Sir Edward T. Campbell. The toast of "British Engineers" was ably proposed by Major Sir Archibald Boyd-Carpenter, and response was fittingly made by Mr. Alan E. L. Chorlton, President of the Institution of Mechanical Engineers, and Sir Cyril Kirkpatrick, Past-president of the Institution of Civil Engineers. The last toast, "The Association of Consulting Engineers," was entrusted to Sir Lynden L. Macassy, and the Chairman, Mr. A. M. Sillar briefly replied.

Force, Shrink and Expansion Fits.*

By ROBERT RUSSELL, B.Sc., A.M.I. Mech. E.

Introduction.—The transmission of power by elements having cylindrical mating surfaces has for long been successfully effected by an assmbly in which keyways and key seats were cut on the surfaces and a key inserted between the elements. The development of high-speed machinery, however, created a set of conditions in the hollow element or wheel which could not be met successfully by such an assembly. A tendency for it to become loose upon the shaft or solid element, due to an increase in the size of the bore under centrifugal action, could only be successfully prevented by an assembly which induces in the material surrounding the bore elastic strains and stresses in excess of those to which the wheel would be subjected at the maximum speed of rotation. Such an assembly, making use of the elastic properties of the mating materials, would require the free diameter of the solid element to be slightly bigger than the free diameter of the hollow element. Where there is a fit allowance or difference in the free diameters of the cylindrical mating surfaces, the assembly may be made, by heating the outer or hollow element, as a shrink fit; or it may be made by pressing the hollow element over the solid element as in force fit practice. The elastic grip between the mating elements may also be established by cooling the inner or solid element to an extremely low temperature by immersion in a refrigerant, and then allowing it to grip the hollow element as an expansion fit.

Information is required which would lead to the standardisation of the procedure adopted in the making of such assemblies. The failure of the early turbine discs to maintain their grip due to the reduction of the radial interface pressure to zero, the loosening of drums on shafts due to temperature effects, the slipping of pins and journals in crank webs, and the loosening of tires on locomotive wheels have all resulted in a technique of a higher order in making the fit assembly. Workshop practice to-day is, however, so varied as to suggest that differences still exist in the minds of engineers regarding certain aspects of the subject, a state of affairs which is far from satisfactory. The nature of the finish of the mating surfaces differs widely. They may be machined, but unpolished, and not very smooth, they may be turned or ground, or they may be dry-scraped or wet-scraped and given a high polish. The fit allowance would appear to vary within wide limits. For example, a certain shrink fit assembly has fit allowances ranging between 1 and 1·75 thousandths of an inch per inch diameter for the same quality of material, and the results appear to be equally successful, despite the fact that at the higher fit allowances the stress induced in the bore layers is well above the elastic limit of the material.

Failure of Material Under Combined Stress.—It is usual, in the case of an assembly having cylindrical mating surfaces and dependent upon the elastic properties of the materials for its grip, to employ Lamé's thick cylinder theory to determine the magnitude of the stresses induced in the hollow and solid elements. The theory is so well known in connection with force and shrink fits that it need only be briefly referred to.

The magnitude of the radial interface pressure p_r and, hence, of the hoop stress induced in the bore layers of the hollow element, will depend upon the difference in the free diameters of the mating elements. If S is the fit allowance inducing p_r, R and r the outer and inner radii, and E Young's Modulus for the material, then:

$$\frac{S}{2}=p_r\,\frac{r}{E}\left(\frac{R^2+r^2}{R^2-r^2}+1\right) \quad . \quad . \quad . \quad . \quad (1)$$

The radial and hoop stresses are a maximum at the mating surface and vary throughout the wall thickness of the element, reaching minimum values at the outer surface. The maximum value of the interface radial pressure, however, will be limited by the failure condition of the layers at the bore surface under combined stress. Many theories have been advanced for ascertaining the criterion of failure of materials under such conditions.

Force Fit Assembly.—As an illustration of force fit practice, the assembly of wheel centres on axles for the standard 12-ton mineral wagon will be considered. The axles are made either of acid open-hearth or basic open-hearth steel with an ultimate tensile stress of 35–40 tons per square inch.† The wheel seat, according to specification, must be turned with a smooth finish, and be either parallel or having a taper of not more than $^{3}/_{1000}$in. The boss of the wheel centre must be bored with a smooth finish, and the hole and wheel seat coated with a suitable lubricant, preferably pure rape oil. The wheel centre, when untired, is forced on to its seat by hydraulic power with a pressure of not less than 60 tons and not more than 80 tons. For tired wheel centres it is assumed that a load is imparted to the wheel boss by the shrinkage of the tire on the rim and an extra 10 tons in each case is allowed. It is important to note that in this assembly the Railway Clearing House specify a minimum and maximum axial tonnage, but make no reference whatever to a force fit allowance for the mating elements.

Quality of Material in Elastic Grip Assemblies.—As has been mentioned, the Railway Clearing House specify a tonnage instead of a fit allowance in pressing wheels on their seats. This tonnage is obtained in practice by a method of trial and error. Wheels are bored with a given fit allowance, based on experience of similar work, and the fit which gives the specified tonnage determines the dimensions for the mating assembly. The specification and the method of conforming to it are both open to serious objection. If no consideration is given to the physical properties of the material, the fit allowance may result in an overstressed boss and a diminished grip between the mating elements. Test pieces taken from the web of wheel centres must, according to the specification, show a tensile breaking strength of not less than 28 tons per square inch. No reference is made to the elastic limit or yield point of the material. Yet the stress-strain proportional limit is the factor which should determine the fit allowance and the suitability of the material for an elastic grip assembly.

In order to get some idea of the quality of the material surrounding the bore, four tensile test pieces were machined from each of the bosses of wheel centres made from eight different casts. Two were taken circumferentially from the wheel boss and at right angles to one another. Two were taken from the boss parallel to the wheel bore and also at right angles to one another. The average values obtained from the four tests of each cast showed a great variation in the quality of the steel. Values as low as 24·38 tons per square inch were obtained, and in three casts only did the material give a minimum strength in excess of 28 tons per square inch.

The load-extension diagrams indicated that the yield point of the material was not clearly defined. There was evidence that the material at certain points of the boss had been influenced by the mechanical processes in manufacture. It was apparent that the material had a low elastic limit and yield point. Test readings gave elastic values of 6·4 to 9 tons per square inch, and yield point values of 11 to 16·04 tons per square inch.

This particular assembly was made with a force fit allowance of from $^{10}/_{1000}$in. to $^{12}/_{1000}$in., and to give some idea of the magnitude of the stresses induced in the boss by different fit allowances, Table I. has been compiled.

TABLE I.—*Stresses Induced by Various Fit Allowances.*

Force fit allowance.		Radial pressure.	Hoop Stress.	Principal stress theory	Principal strain theory	Shear stress theory	Strain energy theory
S/d thousandths of an inch per inch diameter.	S thousandths of an inch.	p_r tons per sq. in.	f_r tons per sq in..	f_L tons per sq. in.	f_L tons per sq. in.	f_L tons per sq. in.	f_L tons per sq. in.
0·75	4·13	3·242	6·78	6·78	7·75	10·02	8·33
1·00	5·5	4·322	9·03	9·03	10·33	13·36	11·11
1·25	6·88	5·403	11·29	11·29	12·91	16·69	13·89
1·50	8·25	6·483	13·55	13·55	15·50	20·04	16·66
1·75	9·73	7·563	15·81	15·81	18·07	23·37	19·44
2·00	11·0	8·644	18·06	18·06	20·65	26·71	22·21
2·25	12·38	9–725	20·32	20·32	23·25	30·05	25·00

Substituting for R and r in equation (1), the interface radial pressure intensity is given by:

$$p_r=4322\,\frac{S}{d}$$

and the hoop stress at the bore layer by

$$f_r=2·09\,p_r.$$

Elastic failure condition under the combined stress due to p_r and f_r is given by

$2·09\,p_r=f_L$ (Maximum principal stress theory).
$2·39\,p_r=f_L$ (Maximum principal strain theory).
$3·09\,p_r=f_L$ (Maximum shear stress theory).
$2·57\,p_r=f_L$ (Maximum strain energy theory).

It will be observed that with a force fit allowance of 1·75 thousandths of an inch per inch diameter, which gives approximately the minimum difference in the free diameters of the mating elements in this assembly, the elastic limit of the material has been greatly exceeded. There can be no doubt that the assembly has been made under plastic flow conditions which may penetrate well into the wall thickness of the wheel boss and lead to a condition of permanent set. If so, it would be reasonable to expect a low back-pressure tonnage and evidence of an overstressed boss on dismantling. A number of the wheels were put under test and many low back-pressures were recorded.

Careful measurements, made as already described, gave an average difference in the free diameters of the mating elements, or residual force fit allowance, of about $^{5}/_{1000}$in. This is approximately one-half the assembly fit allowance of from $^{10}/_{1000}$in. to $^{12}/_{1000}$in. A similarity of the surface form of the hollow element to that of the solid element gave in many cases further evidence of an overstressed boss condition. The overstrain of this element in some cases resulted in the bore diameter at the leading face of the boss being bigger than the wheel seat by $^{1}/_{1000}$in. to $^{2}/_{1000}$in. A pronounced out-of-roundness and out-of-straightness of the solid elements were also observed.

The author suggests that in specifying that the test piece is to be taken from the web of the wheel centre a part has been selected which will give higher elastic limit and yield point values than those obtained from the wheel boss. Doubt may be expressed as to which of these two parts is more severely stressed under running conditions.

It may be well, at this stage, in view of the experiments to be described later, to consider the fit allowances employed and the magnitude of the stresses induced in an important shrink fit assembly, a built-up crank shaft. Consider the web having dimensions such that $R/r=1·876$. Substituting R and r in equation (1), the interface radial pressure intensity is given by

$$p_r=4785\,\frac{S}{d}$$

and the hoop stress at the bore layer by

$$f_r=1·8\,p_r.$$

The elastic failure condition under the combined stress due to p_r and f_r is given by

$1·8\,p_r=f_L$ (maximum principal stress theory)
$2·1\,p_r=f_L$ (maximum principal strain theory)
$2·8\,p_r=f_L$ (maximum shear stress theory)
$2·3\,p_r=f_L$ (maximum strain energy theory).

The webs in such an assembly are generally made from a 28 to 32-ton rolled slab steel and the shrinkage allowance employed by crank shaft makers is between 1 and 1·75 thousandths of an inch per inch diameter. It will be observed from Table II. that a shrinkage allowance of 1·75 thousandths of an inch per inch diameter would require the elastic limit to be not less than 19·26 tons per square inch. An elastic condition of this order obtained in the case of the force fit assembly having a fit allowance of 1·75 thousandths of an inch per inch diameter.

This is a figure associated with steel of high quality and is much in excess of that obtained from a 28 to 32-ton steel. Load extension curves obtained from test pieces taken from a steel bloom before being rolled into slabs for crank webs gave an average elastic limit value of 9·5 tons per square inch. This material may be regarded as representative of the quality of the steel in the centre part of the crank web which has had comparatively little work done on it during rolling. The high shrinkage allowance, therefore, adopted by some crank shaft makers is bound to introduce plastic or semi-plastic conditions well into the wall thickness of the web material. It is suggested, based on experimental evidence to be discussed later, that a successful shrinkage assembly may be effected with the wall thickness of the hollow element entirely within the elastic range of the material.

ELASTIC GRIP ASSEMBLY EXPERIMENTS.

Nature of Surfaces.—The surface generated during the boring of the hollow element or the turning of the solid element is always a helical groove. The depth of the groove depends on the condition of the cutting edge and the feed of the tool. There are differences of opinion regarding the effect of the finish of the mating surfaces. Ideal conditions would appear to be afforded by smooth surfaces, which would make possible the greatest amount of bearing contact between the mating elements. Surfaces that are not too smooth, however, are recommended by some as providing the best protection against axial slip. Others suggest that the tops of the little ridges of such surfaces will be crushed during shrinkage, or sheared off in a force fit operation, and that the back pressure would be less than for elements with smooth surfaces. There is evidence to show that the degree of smoothness of the surfaces resulting from different machining operations has practically no effect on the coefficient of friction and the force necessary to bring about slip.

Good modern machine shop practice gives a degree of finish to mating surfaces, which is more or less free from tool ridges. Many such surfaces, however, have a pronounced out-of-straightness. It is suggested, therefore, that for elastic grip assemblies greater attention should be directed to the need of a higher degree of accuracy in the generation of the cylindrical mating surfaces, a condition more difficult to attain than a high surface finish. This would be facilitated by carrying out the final metal removal operation by grinding.

EFFECT OF LUBRICANT ON PRESSING-ON LOAD.

Workshop experience of the influence of a lubricant in preventing the mating surfaces of a force fit assembly from being scored or destroyed in making or breaking the fit, together with the evidence presented by R. M. Deeley, M.I. Mech. E., that the static coefficient of friction between the surfaces of different metals when lubricated depends upon the oiliness of the lubricant, suggested that in a force fit assembly the lubricant employed might have an appreciable influence on the pressing-on load. It was therefore decided to carry out tests on force fit assemblies, with some of the earlier vegetable and animal oils used as lubricants by the engineer, together with the later types of mineral and blended oils.

Tests to Investigate Effect of Lubricant.—Six tests were carried out with the same pin and collar having mating dimensions of 1·5038in. and 1·5030in. respectively, giving a difference in the free diameters of the mating elements of 0·8 thousandths of an inch. It can be shown that a force fit allowance of this order will induce a radial pressure intensity at the mating surfaces of 2·7 tons per square inch and a hoop stress intensity at the bore layer of 4·51 tons per square inch.

Test 1.—Elements assembled and dismantled with film of Bayonne oil on mating surfaces.

Test 2.—Elements assembled and dismantled with film of sperm oil on mating surfaces.

Test 3.—Elements assembled and dismantled with film of "Texaco" motor oil (heavy) on mating surfaces.

Test 4.—Elements assembled and dismantled with film of rape oil on mating surfaces.

Test 5.—Elements assembled and dismantled with film of graphite and engine bearing oil on mating surfaces.

Test 6.—Elements assembled and dismantled with film of cutting lubricant on mating surfaces.

The lubricant used in test 6 was an emulsion, suitable for general lathe work, made by mixing a cutting compound with water. Cutting oils and cutting compounds are used in metal machining operations not only to dissipate the heat generated and wash away the cuttings, but also to give a smooth finish and prevent rusting. The dimensions of the mating surfaces were measured before and after each test and these showed no signs of change. This is an essential condition, of course, to any successful investigation of the influence of the lubricant on the force fit tonnage. It was made possible by the use of elements having good mating surfaces and a relatively small force fit allowance. It is surprising that after assembling the elements six times there was no evidence of a tendency for the bore dimensions to become bigger or the pin dimensions to become smaller. A critical examination of the mating surfaces gave no evidence of improved bearing contact, a condition which would have influenced the pressure necessary to make the assembly.

Load diagrams on a base of bore length are given in Fig. 1 and indicate clearly the remarkable influence of the lubricant on the force necessary to make an assembly of the elements. The values range from 5·1 tons with rape oil as a lubricant to 13·55 tons with Bayonne oil. This represents an increase of 166 per cent. in the pressing-on load due to a difference in the nature of the lubricant.

---

* The Institution of Mechanical Engineers. Read in Manchester on Thursday, December 7th.—Abridged.

† "Specification for Standard 12-ton Mineral Wagon," Railway Clearing House, April, 1923.

The coefficient of friction for each assembly was obtained by the equation

$$F = \mu \, p_r \, . \, 2\pi r \, . \, l \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where F is the maximum pressing-on tonnage, l the length of the hollow element, and μ the coefficient of friction. The values obtained by this method of approach to boundary lubrication, given in Table III., are of a very high order and greatly in excess of those obtained by the Deeley machine using the same lubricants but different mating materials. It was found, however, that the ratios of the maximum load obtained with the various lubricants to the maximum load obtained with rape oil were of the same order as the ratios of the coefficients of friction obtained by the Deeley machine.

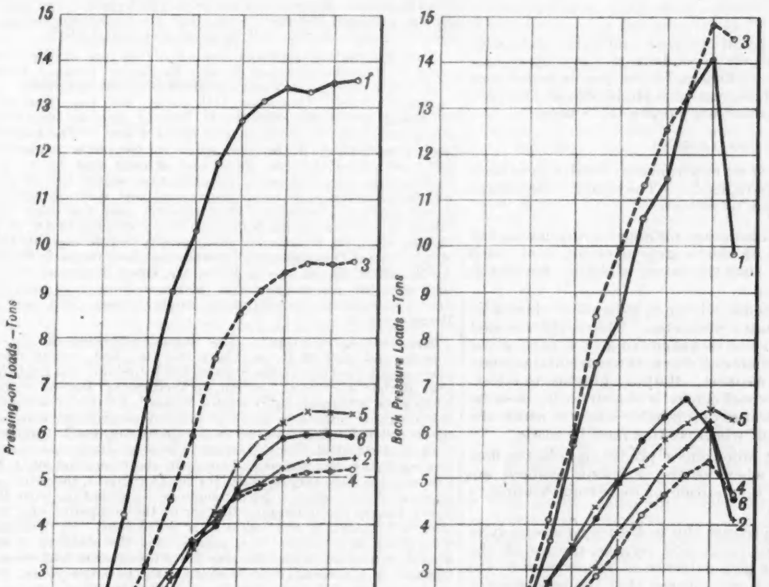
* *Jl.* Roy Tech. College, Glasgow, 1931, Vol. II., page 495.

In no case was an assembly made by a gradual slipping of the mating elements. The load gradually rose until slip took place, when there was a sudden fall in the oil pressure. This gradually rose again until a further slip and another drop in the oil pressure occurred. With those lubricants having a pronounced oiliness the slips took place without any noise until the assembly was half complete, after which slipping was accompanied by a light bumping on the sudden fall in pressure, which became more pronounced towards the completion of the fit. Periodic slips of much greater magnitude and accompanied by heavy bumping were noticed throughout the complete assembly of the elements when a lubricant not having an oiliness property was employed.



Test 1.—Bayonne oil.
Test 2.—Sperm oil.
Test 3.—"Texaco" motor oil (heavy).
Test 4.—Rape oil.
Test 5.—Graphite and engine bearing oil.
Test 6.—Cutting lubricant.

Test F.—Force fit assembly. Bayonne oil film on mating surfaces.
Test E.—Force fit assembly. Rape oil film on mating surfaces.
Test D.—Expansion fit assembly. Rape oil film on mating surface of hollow element.
Test B.—Shrink fit assembly. Rape oil film on mating surface of solid element.

FIG. 2—LOAD DIAGRAMS FOR FORCE FIT ASSEMBLY TESTS

It was thought that the "skin" or thin layer of grease that tends to gather on the surface of an element during or after machining operations might in some way influence the effect of the lubricant in an assembly process. After completing the back pressure test in which the cutting compound was used as a lubricant, the surfaces of the pin and collar were wiped only with a clean cloth and then reassembled with rape oil as the lubricant. But the closeness of the readings obtained with these two lubricants and perfectly clean surfaces prevented any definite conclusions being reached. It was therefore decided to use two lubricants giving a high and a low load respectively with perfectly clean surfaces, and Bayonne oil and rape oil were selected as providing the best means of analysing this "skin" effect.

Five tests were carried out with the same pin and collar having a force fit allowance of 0·6 thousandth of an inch. From them it would appear that the "skin" or invisible primary film which may have been formed on the mating elements which were reassembled after having been treated with a clean cloth only, had no effect on the characteristic influence of the lubricant on the force fit load.

EFFECT OF ASSEMBLY METHOD ON THE QUALITY OF GRIP.

Shrink Fit Assembly Tests.—Experiments were carried out with two pins and two collars having a fit allowance of $^1/_{1000}$in. The collars were heated by a gas burner until a hole clearance was obtained, as measured by a gauge, which would just allow the collar to slip over the pin.

Test A.—The elements were assembled with the mating surfaces perfectly dry and free from film. The mating surface of the hollow element had just the slightest touch of colouring due to the heat applied.

A 20-ton Amsler testing machine failed to separate the elements and the back pressure test was completed by a 100-ton Avery horizontal testing machine. An initial load of 28·8 tons was required to produce slip, but a much greater axial load was required to maintain this condition. The clean mating assembly had allowed seizure to occur so strongly that relative motion pulled the surface particles of each solid out of position. The mating surfaces were torn to such a depth that no further use could be made of the elements. The quality of the grip established was such that the taper part of the solid element was shorn off, and left firmly embedded in the surface of the hollow element.

Test B.—The hollow element was prepared as in test A. The solid element or pin had a thin film of rape oil on the surface.

The back pressure test was carried out on the Amsler machine and a tonnage of 8·5 tons was recorded when slip occurred. This pressure dropped immediately to a value of 2·8 tons and then gradually fell off as the separation of the elements proceeded.

Very good surface conditions obtained after dismantling the elements. There was no sign of even the tiniest hairline scratch, but there was evidence that the mating surfaces had been separated by a lubricating film. The darkest colour in the bore surface could be lifted off with the lightest touch of the finger tip, revealing the bright steel mating surface underneath. It was decided, since the surfaces were in perfect condition and there was no change in the mating dimensions, to reassemble these elements under different conditions.

Test B_1.—The elements were reassembled with the mating surfaces perfectly dry and free from film, as in test A.

There was a slight creaking when the load applied reached 8·5 tons, but there was no measurable sign of slip within the load capacity of the Amsler machine. Slip took place when a load of 28·2 tons was reached on the 100-ton testing machine, and an increase in load was required, as in test A, to produce further slipping between the elements. The mating surfaces were very badly torn, large pieces of each mating element being pulled out of position. The grip was so well established that, as in test A, part of the solid element was shorn off during withdrawal and left firmly fixed to the surface of the hollow element.

These experiments demonstrate that a primary film may separate the elements in a shrink fit assembly, even when mated under a high radial pressure intensity. The results indicate that the presence of such a film will result in an enormous reduction in the axial resistance of the elements to slip. It is important to note that many builders of crank shafts make such adsorbed film conditions possible by lubricating the pin or journal in the hope of avoiding pre-seizure of the elements on assembly.

Assembly by Expansion Fit.—By this method the solid element is cooled to an extremely low temperature by immersing it in a refrigerant. This brings about a reduction in the diameter which will allow of it being slipped easily into the hole of the hollow element. The solid element, in returning to normal temperature conditions, expands, and the elastic strains and stresses induced in the elements result in an effective grip being established. Liquid oxygen, whose boiling point is at the extremely low temperature of −190 deg. Cent. (−310 deg. Fah.), was used as a cooling agent. The amount of contraction possible, which sets a limit to the maximum possible fit allowance by this method of assembly, is determined by the temperature at which the cooling agent evaporates. The solid element should just be a push fit when fully cooled. Although the shape of the part may influence the time necessary to bring about the lowering of the temperature, the liquid requirements are determined by the material and weight of the part immersed. These requirements can be reduced if the refrigerating capacity of the vapour which comes off the oxygen as it evaporates is usefully employed in pre-cooling the parts before immersion.

Expansion Fit Assembly Tests.—Experiments were carried out with two pins and two collars, having a fit allowance of $^1/_{1000}$in. The solid elements were cooled by liquid oxygen to a temperature of approximately −310 deg. Fah., which allowed of the pin in each case being easily slipped into the hole of the collar.

Test C.—The elements were assembled with the mating surfaces perfectly dry and free from film. The pin, after removal from the refrigerant, was rubbed hurriedly with a clean cloth before making the assembly.

The back pressure test was carried out on the Amsler machine, and a load of 4·35 tons was recorded when slip occurred. This pressure rose to a maximum of 5·05 tons, and an average pressure of a little over 4 tons was required to maintain a condition of slip over the first half of the operation. The mating surfaces were in perfect condition. A few extremely fine hair lines could be seen, but not felt, on the bore surface, and these, if rubbed lightly with the finger tips, could be removed.

Test D.—The solid element was prepared as in test C. The hollow element had a thin film of rape oil on the bore surface.

The back pressure test gave a load of 3·425 tons when slip occurred. The pressure then dropped suddenly, rising afterwards to a value of 3·15 tons, after which there was a gradual drop.

The surface conditions were excellent after breaking the fit. There were a few fine hair lines on the mating surface of the hollow element, similar in character to those described in test C. It was decided, since there was no change in the mating dimensions, to reassemble these elements under different conditions.

Test D_1.—The elements were re-assembled by shrinkage with the mating surfaces perfectly dry and free from film.

Slip took place when a load of 20·86 tons was reached on the 100-ton testing machine. A much greater axial thrust was required, however, to effect further separation of the elements. Seizure at the points of contact was so strong that slip caused the surface particles of each element to be pulled out of position and these were rolled and dragged during further separation of the elements so that the mating surfaces were very badly torn.

The low tonnage obtained in test C, together with the excellent condition of the mating surfaces after dismantling, would suggest that the solid elements were separated by a very thin film and failed to make actual contact. Although an endeavour was made to have the surfaces perfectly dry and free from film at the instant at which the assembly took place, there can be no doubt but that a water film formed on the pin by frosting during the expansion period. This film would act as a lubricant and the friction during slip of the elements would be that due to two primary water films, one on each mating surface. As already pointed out, the temperature of the refrigerant sets a limit to the maximum possible fit allowance by this method of assembly, and it would appear that a limit is also set to the quality of the grip by the water film produced during frosting. The author knows of no effective means, unless the operation is carried out under ideal dry air conditions, of getting rid of the film produced during the period of expansion. This would indicate that this method is limited to an assembly of units in which the hollow element takes only a small proportion of the maximum thrust or torque transmitted by the solid element.

TABLE IV.

Test.	Assembly method.	Surface condition.	Torsional slip, spring balance reading.	Axial slip, tons.	Coefficient of friction.	
					Torsional.	Axial.
G	Force fit	Rape oil film	90 lb. at first slip .. 95 lb. at second slip	2·6	0·3	0·263
H	Shrink fit	Rape oil film	100 lb. at first slip .. 80 lb. at second slip	2·6	0·29	0·263
I	Shrink fit	Perfectly dry and free from film	260 lb. at first slip .. 260 lb. at second slip	12·8 (slight slip of pendulum) 20·8	0·906	1·295

Force Fit Assembly Tests.—Experiments were carried out with two pins and two collars having a fit allowance of $^1/_{1000}$in. The pressing operations were carried out on a 20-ton Amsler testing machine operated under oil pressure. The machine was regulated to effect a complete assembly or dismantle the elements in approximately twenty-five minutes. Two different lubricants were used.

Test E.—Elements assembled with rape oil film on mating surfaces.

Test F.—Elements assembled with Bayonne oil film on mating surfaces.

The load diagrams on a base of bore length for the complete separation of the elements are shown in Fig. 2. The back pressure loads for the same film conditions by the other two assembly methods are also shown and provide a basis of comparison.

The load diagrams secured would suggest that a force fit assembly of elements using as a lubricant Bayonne oil, a mineral oil, may afford a quality of grip far superior to that established by even a shrink fit or expansion fit assembly if the mating surfaces are separated by a film with a distinct oiliness characteristic.

Torsional Resistance to Slip.—The quality of the grip established between elements under the different conditions of assembly considered has been measured by comparing the axial resistance of the elements to slip. It was thought advisable to make a few assemblies to compare the grip by the torsional resistance of the elements to slip. It was hoped that this would also provide sufficient data for comparing the axial and torsional coefficients of friction for the different assembly conditions. The solid element, in this case, was supported horizontally between centres and firmly fixed at one end. The hollow element had two notches cut on the outer surface, and the lever arrangement was made to engage with the notches cut in the hollow element without transmitting any appreciable load to the outer surface. The pull at the free end was applied by pulley blocks and the value, when slip occurred, was accurately determined by the sudden drop in the spring balance reading. Clean mating surface conditions were obtained in each case by the methods described in previous tests.

Tests to Investigate Torsional Slip.—Three tests were carried out with the same pin and collar having a fit allowance of 0·5 thousandth inch. A fit allowance of this order will induce a radial pressure intensity at the mating surfaces of 1·68 tons per square inch.

Test G.—The force fit assembly was made with a rape oil film on the mating surfaces.

The pull was applied at 60in. from the axis of rotation and initial slip took place when a pull of 90 lb. was recorded on the spring balance. The pull was increased to 95 lb. before further slip occurred.

The back pressure test was carried out on the Amsler machine and a load of 2·6 tons was recorded when slip occurred.

There was no change in the mating dimensions, after separation, and the surfaces were found to be in a very good condition. This allowed of a further assembly of the elements.

Test H.—For the shrink fit assembly the elements were re-assembled with a rape oil film on the mating surface of the solid element.

Initial slip took place when a pull of 100 lb. was recorded on the spring balance. Further slip was possible, however, with a pull of 80 lb.

A back pressure of 2·6 tons was required to induce initial slip.

No change was found in the mating dimensions after separation, but there were a few thin grooves along the surface of the hollow element. The solid element had still a very good mating surface. An examination of the hollow element indicated that the surface, although bearing a few score lines, would allow a further assembly to be successfully made.

Test I.—The elements were again re-assembled as a shrink fit with the mating surfaces perfectly dry and free from film.

Initial slip took place when a pull of 260 lb. was recorded on the spring balance.

The back pressure test was carried out on the Amsler machine, and although a slight slip in the pendulum was noticed at 12·8 tons there was no measurable slip between the elements within the capacity of the machine. The back pressure test was completed on the 100-ton testing machine and axial slip took place at a load of 20·8 tons. The mating surfaces were very badly torn, large pieces of each mating element being pulled out of position.

The torque that an assembly fit is capable of transmitting is based by designers on an assumed coefficient of friction. This value, unfortunately, varies over a wide range and may lead, if a low or "safe" coefficient is assumed, to excessive fit allowances and possible failure.

The values given in Table IV. confirm a previous finding that the quality of the grip, and hence the coefficient of friction, is greatly dependent on a mating surface film condition. The coefficient of friction in test I was based on the load which caused a slight slip in the pendulum of the testing machine, namely, 12·8 tons.

CONCLUSIONS.

A few findings based on experimental results have been stated in previous paragraphs. The main conclusions, briefly summarised, are as follows :—

(*a*) The degree of accuracy obtained in machining the mating surfaces of an elastic grip assembly is of much greater importance than the nature of the machine finish of the surfaces.

(*b*) The materials used in such assemblies should be specified by their elastic properties. The test pieces used for this purpose should be taken from that part of the element where the material, due to the particular method of manufacture, is weakest. Railway practice in selecting the web of a wheel centre is shown to be unsatisfactory as failing to provide reliable data on which the force fit assembly of wheel centres may be made.

(*c*) Excessive fit allowances producing plastic flow conditions in the wheel centre or hollow element are shown to produce a condition of overstrain leading to failure of the grip.

(*d*) The load to produce slip in a force fit assembly of elements is greatly influenced by the nature of the lubricant. Results give evidence of an increase in the load of 166 per cent. and suggest that the resistance to axial slip is not altogether a question of the fit allowance.

(*e*) The "skin" or film, if a fluid, which may gather on the mating surfaces before assembly, may be removed without the use of solvents, and the resistance to slip on assembly is controlled by the nature of the lubricant.

(*f*) The assembly method may not determine the quality of the grip. Results show that this is greatly dependent on the surface film condition which may separate the mating surfaces after assembly. Such surface films, although more likely to be present under certain conditions of assembly than in others, may be equally operative under all three.

(*g*) A successful shrinkage assembly may be established with a fit allowance producing stresses well within the elastic range of the material, if the mating surfaces are perfectly dry and free from film.

(*h*) There is no evidence that the "torsional coefficient of friction is greatly in excess of the axial coefficient of friction" sometimes quoted.

The author feels that a great deal of experimental work remains to be done on the effect of surface films on the grip in an elastic assembly of elements. It remains to be determined whether a period of time would have any effect on the great variation in the axial resistance to slip produced by different lubricants in force fit assemblies. In the tests described the elements were dismantled immediately after the assembly was made.

Experiments are still required to determine whether the nature of the lubricant would be as effective if the assembly unit was subjected to shock conditions, as represented by end blows or sudden torque impulse. Skin effect could be further examined by a consideration of the effect on the load when elements with perfectly clean surfaces and various lubricants are re-assembled, the mating surfaces having been wiped thoroughly with a clean cloth.

CONTRACTS AND ORDERS.

The Editor is always happy to print short announcements of contracts and orders in this column provided they are sent to him in time to have news value and that they are likely to interest readers.

GREENWOOD AND BATLEY, Ltd., Leeds, have recently received an order from the Fife Coal Company, Ltd., for an 8-ton "Greenbat" mining locomotive. This is the third engine of this type purchased by the company.

SIR W. G. ARMSTRONG WHITWORTH AND CO. (ENGINEERS), Ltd., have been given an order by the G.I.P. Railway for a Diesel-electric railcar for use on the Central Provinces Railway. It will be equipped with a 122/140 B.H.P. engine.

HARLAND AND WOLFF, Ltd., have been entrusted with the building of a target-towing tug for the War Office. It will be about 112ft. in length, and will be propelled by oil engines of the Harland-B. and W. type, and will be laid down at Govan, whilst the machinery will be constructed at the builders' Finnieston Diesel Engine Works, Glasgow.

C. A. PARSONS AND CO., Ltd., of Newcastle-on-Tyne, have received from the East Rand Proprietary Mines, Ltd., of South Africa, an order for a turbo-alternator of 20,000 kW capacity, complete with condensing plant. The turbine will develop its power in a single cylinder exhausting into a condenser of the inverted type. The alternator is of special interest, for it will have a two-core concentric winding and will generate current at the unusually high pressure of 22,050 volts.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

PETER STUBS, Ltd., Warrington, have appointed Messrs. J. Penny and Son, Argyll Works, Alma-street, Smethwick, as their representatives for the sale of steels in the Birmingham area.

ANDREW CARNEGIE RESEARCH FUND.—The Council of the Iron and Steel Institute is prepared to make annually a limited number of grants from the Research Fund founded by the late Mr. Andrew Carnegie in aid of metallurgical research work. The object of the scheme is not to facilitate ordinary collegiate studies, but to enable students who have passed through a college curriculum or have been trained in industrial establishments to conduct researches on problems of practical and scientific importance relating to the metallurgy of iron and steel and allied subjects. Candidates, who must be under thirty-five years of age, must apply before the end of next February on a special form to be obtained from the Secretary of the Iron and Steel Institute. The value of the grant will depend on the nature of the proposed research work, but the maximum amount granted in any one year will, as a rule, not exceed £100.

THE ENGINEERS' GERMAN CIRCLE.—The last of the 1933 series of lectures arranged by the Engineers' German Circle took place at the Institution of Mechanical Engineers on Monday evening, December 11th, when Dr. Ing. Eberhard Westphal, of the Schichau Werft, Danzig, gave an illustrated lecture on "The Improvement of Ships' Plans." The lecturer dealt principally with the arrangement of the public rooms and cabin accommodation in ships, and showed that by careful re-planning a considerable simplification could be effected which made the ship more economical and safer in service. About forty-five members were present, and the chair was taken by Mr. W. Roylands Cooper, in the absence of Dr. S. J. Davies, who, on Wednesday last, gave a lecture on "Modern Motive Power Developments" before the sister Circle in Berlin. As Mr. H. P. Spratt was in Paris, Mr. Ernst Schneider kindly took over the secretarial duties for the evening. An informal dinner was afterwards held at the Anglo-German Club, Carlton House-terrace.

THE HOUSE OF LISTER.—The annual gathering of agents, friends, and staff of R. A. Lister and Co., Ltd., which takes place about the time of the Smithfield Club Show, was held this year at the Café Royal, London, on Wednesday, December 6th, when some 500 guests sat down for dinner. A letter of welcome, the menu, a timetable, and the musical programme wrapped up in roll form and inserted in a napkin ring made from the teak timbers of H.M.S. "Terrible," was awaiting each guest. During dinner, Mr. Robert B. Lister, the chairman, and Mr. J. H. Thomas, the Secretary of State for the Dominions, the principal guest of the evening, held a telephone conversation with Mr. Percy Lister, the managing director of the company, who was then in Chicago, in the course of a world tour. Mr. Thomas, who spoke in a serious vein, commended the stability of the British constitution, and the way the whole nation had worked together to overcome the difficulties of the past two years. He said that Great Britain was the only nation which was in a position to say that the worst was over, and he was proud that this Christmas would find more than 800,000 more unemployed at work. The toast proposed by Mr. Thomas was that of "British Industry," and Mr. R. B. Lister responded, after which the usual toast of "The House of Lister" was given by Mr. H. F. Pash and acknowledged by Mr. Sidney Howard, the principal actor at the Aldwych Theatre. During the evening a musical programme was given by the new Lister military band. After dinner the guests left the Café Royal in private coaches and proceeded to the Aldwych Theatre.

THE BRITISH OXYGEN COMPANY, LTD.—A pleasing function took place at the Café Royal on Friday last, December 8th, when some 370 members of the staff from nearly forty of the various works of the B.O.C. and allied companies throughout the country, gathered at the annual dinner of the London staff of the British Oxygen Company, Ltd. At the dinner a presentation was made to Mr. K. S. Murray, to mark his retirement at the end of 1933 from the chairmanship and managing directorship of the company. The presentation took the form of an album containing an illuminated address followed by the signatures of over 2500 directors, members of the staff, and workpeople of the main and allied companies in Great Britain, together with a silver cigar box, suitably inscribed, and filled. It is a fitting tribute to Mr. Murray that the illuminated address is followed by the signatures, done in facsimile, of every man and woman at present in the company's employ in over forty works and offices throughout the country. After meeting the expense of the personal gift to Mr. Murray, a sum of about £300 remained from the funds collected, and by Mr. Murray's express desire this will be used in some way which shall be of benefit to the staff and workpeople of the company. The presentation was made by Mr. H. J. Chadd, the company's district manager of the Midland and South-Western areas, who joined the original Brins Oxygen Company in Westminster in 1886, about the same time as Mr. Murray, and by Mr. Charles Sharp, who is Mr. Murray's oldest colleague on the board of directors of the company. The toast of "The British Oxygen Company" was proposed by Mr. Murray, and replied to by Mr. J. L. Buchanan, while Mr. Frank Payne proposed the toast of "The Chairman." A feature of the evening was the presence of the pipers of the 1st Battalion of the Scots Guards, who piped Mr. Murray to his place, and took part in providing the music for dancing which followed the dinner. The evening was a most enjoyable one in every respect.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The Pig Iron Market.

Seasonal influences have affected this market and trading has been quieter during the past week. Some heavy contracts were placed recently, and although the specifications against these are reaching the producers on a satisfactory scale, current business seems to have relapsed into hand-to-mouth buying of small quantities to supplement supplies already arranged for. This is probably a relief to some makers on the North-East Coast, who were finding the pressure of consumers for both near and forward delivery rather inconvenient, as most of the stocks were sold forward and the demand was in excess of the production. It is understood that directly satisfactory supplies of coke can be assured the production of Cleveland iron will be increased. There is no change in prices, No. 1 being quoted at 65s. and No. 3 at 62s. 6d., d/d consumers' works, with an additional 2s. per ton to other consumers in the North-Eastern area. The price to Scottish consumers is based on 65s. 3d. for No. 3, d/d Glasgow, and 62s. 3d., d/d Falkirk. Conditions in the hematite market also are becoming difficult, as although there are still fair stocks at the furnaces, the makers state that a good proportion of these have been sold. The situation is further complicated by the fact that Pease and Partners, Ltd., are to close down two of their blast-furnaces, producing hematite, for repairs, which, it is understood, will take about two months to complete. Most makers are reluctant to accept important forward commitments and point out that in all probability the cost of ore and coke will be higher in the New Year, which may lead to an advance in the price of hematite iron. The Midland makers are in a satisfactory position, since their order books are well filled. The demand has been rather lighter of late, but as the makers regard the price situation as uncertain they are well content to rest for the time being on the orders in hand supplemented by a fair amount of prompt business. There has been no change in the basis prices of Midland irons, which are 62s. 6d. for Northamptonshire and 66s. for Derbyshire No. 3 foundry. The total production of pig iron in this country in November reached 374,900 tons compared with 373,300 tons in October. This was the highest output attained by the British industry this year. The lowest being the February figure of 270,800 tons.

Scotland and Lancashire.

During the last few weeks the situation in the Scottish steel industry has undergone a rapid change for the better owing to the contracts which have been booked for ships, locomotives, wagons, and tubes, and export orders for constructional work abroad. The steel works, however, will not benefit from these orders immediately, and in the meantime operations at some of the mills have declined. An indication, however, of the busy conditions which rule at the light castings department is the decision to re-start the Castle Laurie Foundry in the Falkirk district, which has been closed down for some time. Re-rollers in Scotland are not so well employed as their competitors in England, but they continue to hold their quotation for small bars at £7 5s. for home and £6 5s. for export. The sheet industry is moderately occupied, but export business is difficult, as competition in this department has increased during the past few weeks on the depreciated dollar exchange. The home demand, however, has been steady. Progress at the Lancashire finished steel works continues steady and the new railway orders for wagons and locomotives have already had a beneficial effect upon the position. Business in structural steel is irregular, and whilst some works producing this material are actively engaged, others are anxiously seeking orders to take the place of completed contracts. The demand for small bars shows no signs of relaxing and business in bright-drawn steel, alloys and special steels is well maintained. Steady conditions prevail at Barrow and Workington. The demand for baling hoops, spring steel, and small sections is sufficient to keep the mills busy for some time, and it is estimated that it will be possible to keep the works running at a good rate of operation for several months.

The Midlands and South Wales.

On the whole the situation in the Midland iron and steel markets is satisfactory, and although operations at the finishing mills are irregular, the majority of the works are well provided with orders and some are working at high pressure. A sustained demand for steel strip is a feature of the market, and although fair quantities of Continental material are being imported, practically all the home strip mills are busy and in some cases are behindhand in deliveries. The strength of the demand is indicated by an advance of 10s. per ton in the price of cold-rolled steel strip, which has brought the quotation for close annealed to £20 and for unannealed to £16. The re-rolling mills are well supplied with orders and most of them quote £7 10s. d/d for small bars, although with a good specification it would still be possible to place business at £7 5s. The tonnage of orders going to the Continent has increased of late, but this is scarcely to be wondered at, since the Continental price for merchant bars delivered and duty paid is held at the comparatively low figure of £6 10s. 6d. The steel works are not receiving so much business in bars as are the re-rollers, but the amount of work they have in hand is increasing. The steel makers' quotations range from £7 15s. to £8 10s. Business in joists has been only moderately good, but comparatively small quantities are going to the Continent, as the English steel makers' rebate scheme is very effective in this department. The quieter conditions in the South Wales tin-plate trade have not so far affected production at the steel works. Business from the engineering departments has been rather better, and the demand from the ship repairing yards has also helped to give the market an appearance of activity.

The North-East Coast and Yorkshire.

The activity in the finished steel department of the market has been well maintained, but the usual seasonal influences are beginning to affect the placing of contracts. This is largely the result of the slowing up which takes place before the end-of-the-year stocktaking in most departments of the trade. It is a long time, however, since business has been maintained at such a high rate so late in the season. On the North-East Coast the output of the steel furnaces and the rolling mills has been considerably increased of late and shipbuilding orders placed in this district are expected to provide work for the plate and section mills early into the New Year. This is the more satisfactory, as although production in this district has been on a good scale for some months, the absence of any important shipbuilding orders has been the weak spot in the situation. The departments turning out steel for bridge building are well employed, and on the whole the industry in this district will enter 1934 with better prospects than for years past. Little sign is noticeable in the Sheffield district of the usual seasonal decline. Notwithstanding the heavy demand which has existed for some time for hot and cold-rolled strip and stainless steel sheets, business in this department seems to be expanding. There is also an active request for alloy steels, although in this section the demand is not up to the level of a few weeks ago. A steady increase in business in re-rolled material continues and is one of the features of the position in this district. Latterly there have also been some inquiries for railway material on export account, which, it is hoped, will result in orders.

Current Business.

An order for a 20,000-ton liner has been placed with Vickers-Armstrong, Ltd., at Barrow by the Orient Steam Navigation Company, and orders for two tugs have been awarded to Harland and Wolff, of Govan, by the South African Railways and Harbours Administration. It is estimated that the shipbuilding orders placed on the Clyde in November totalled in value £1,000,000. A contract has been obtained by Sir William Arrol and Co., Ltd., for a swing bridge over the Clyde and Forth Canal, valued at £10,000. The Cleveland Bridge Building and Engineering Company, Ltd., of Darlington, has commenced work on the bridge over the Forth at Kincardine, which, it is estimated, will involve the use of about 4000 tons of steel. The recent improvement in the engineering industry is indicated by a circular issued by Glenfield and Kennedy, Ltd., of Kilmarnock, which states that during the past month they have secured substantial export orders from twenty different countries. The enterprise shown by manufacturers in meeting the requirements of the market is instanced by the Stanton Ironworks Company, Ltd., which has added to its range of Stanton Delavaud spun iron pipes a 3in. diameter spun iron pipe, ¼in. thick, weighing 1 cwt. per 12ft. length. This is sold at a price of 2s. 1½d. per yard, f.o.t. manufacturers' works. Although it conforms to the British Standard Specification and is tested to 200 lb. per square inch, the new pipe is not intended to replace the present thicker 3in. diameter spun iron pipe. The manufacturers anticipate, however, that it will be adopted by many buyers who prefer cast iron pipes to those of other materials. The Department of Overseas Trade announces that the following contracts are open for tender :—New Zealand : Wellington Post and Telegraph Department, 50 miles of tinned copper V.I.R. wire (Wellington, February 13th) ; 75 tons of hard-drawn copper wire (Wellington, February 5th) ; Trinidad : a local architect requires quotations for structural steel and sheet metal work for a new Masonic building ; Egypt : Ministry of Finance, Survey Department, new or second-hand rails up to 3000 tons, totalling 2500 tons of light section and 500 tons of heavy section rails, in any quantities (Egypt, January 20th) ; Ministry of Public Works, steel plates ranging from ⅛in. to ⅜in. thick, 7ft. to 12ft. long and 3½ft. to 5ft. wide;; mild steel T.S. flats and angles, and wagon leaf spring steel (Cairo, January 8th).

The Tin Market.

Interest has been centred this week upon the meeting of the International Tin Committee, which took place in Paris. Following the meeting the text of the agreement governing the International tin control arrangements was issued. The scheme was renewed from October 27th last, and many details were published at the time. The gradual extension of the control of the metal is an interesting feature of the position, and it was announced that the French Government had become a party to the scheme. Apparently, discussions are also taking place with China, South Africa, Burma, and the Belgian Congo, with a view to bringing these tin-producing countries into the control arrangement. The Committee agreed that the export quota from January 1st should be fixed at 40 per cent. of the standard tonnage. The interesting statement was issued that the stocks remaining in the hands of the International Pool amounted at the end of November to 8000 tons. At one time the Pool held stocks of over 21,000 tons of tin, but it was thought that a greater proportion of this had been disposed of than appears to be the case. Although on the whole the arrangement may be regarded as satisfactory, the market was not greatly affected. Prices showed a tendency to advance, but buying, which it was thought might develop, has been only on a moderate scale. America has shown comparatively little interest, and purchases by the Continent, beyond some orders from Russia, have been limited to small quantities. The statistical position is strong, and it is expected that the figures at the end of December will show a further decrease in the visible supply, and that the poor American deliveries in November will be more than made up. It is suggested that the 3350 tons given as the American deliveries last month did not really represent the situation, and that considerable inroads were made into the stocks, so that the position was actually better than was disclosed by the statistics. The stocks in this country continue to be drawn upon and this process is likely to continue for a time.

Copper.

Conditions in the electrolytic copper market have been largely governed by the fluctuations in the American exchange, but of late there has been a rather better tone noticeable, and consumers have shown a greater readiness to buy. The volume of business, judged by normal standards, has been small, but there has certainly been an improvement upon the past few weeks. and this is the more encouraging as it has taken place towards the end of the year, when there is a general reluctance to add to the stocks, in view of the customary stocktaking. The American domestic price has strengthened slightly to 7·75 c. to 8 c. The export quotation has fluctuated somewhat, but most business has been done on the basis of £35 10s. to £35 15s. c.i.f. Europe. Apparently, the copper producers derived confidence from the improvement, slight as it was, and have shown less willingness to follow the market down. In fact, on occasion they have withdrawn their offers when the price showed a tendency to weaken. To some extent the brighter conditions may be due to efforts on the part of dealers to secure shipments before the increased Atlantic freight rates come into operation on January 1st. The most active market seems to have been Germany, but the difficulty of securing payment, owing to exchange restrictions, has held up a certain amount of business. The decrease in the price margin between electrolytic and standard copper to about £3 has led to some buying of the latter by merchants. When the whole position is summed up, however, it has to be admitted that the volume of business in this metal is still on a disappointing scale. Business in the standard market has been steady, although there has been a certain amount of bear covering. The stocks of standard copper, however, are not heavy, and it has not always been easy to obtain the copper required, as warrants are strongly held. In these circumstances, with the market rather more " bear " than " bull," a backwardation has developed of from 2s. 6d. to 3s. 9d. Nervousness has been expressed lest this should be considerably increased. There seems, however, little likelihood of the market developing in this way, since for the time being it appears to be under the control of strong interests who would not favour such a position.

Lead.

Little change has occurred in the conditions which have prevailed in this market for some time. The chief characteristic has been the steadiness of the market and the limited movements of prices. Producers can scarcely be satisfied with the present level of values, and although the Mt. Isa strike still continues, the producing interests can probably afford to regard the situation without anxiety, since stocks are heavy and the present supplies are quite sufficient to meet the requirements of the market. In fact, at current prices there has been some talk lately of mines in other parts of the world closing down or considerably curtailing their output. The demand from consumers has become rather irregular of late, and some good orders have been placed by the chemical engineers. This industry is probably the largest consumer of lead pipes, and normally takes about 20,000 tons per annum. There has also been a fair demand from the building trades, but not upon the scale of recent months. This decline, however, is only to be expected, in view of the advanced season of the year. There is a good demand for lead from the battery makers, but business with the cable industries has become distinctly poor. Prices in the United States have receded, and this may be regarded as an indication that conditions in that market cannot have been much improved by the recovery programme, as the producers are protected from competition by a tariff of 2½c. on imported lead. The stocks in America are estimated at about 175,000 tons, which is almost the same as at the beginning of the year, although in the interval they touched a considerably higher figure.

Spelter.

At the end of last week this market developed a slightly firmer tone, but this was not maintained, and prices again developed an easier appearance. Consumption has not been upon a satisfactory scale for some time. Probably the brass trades have been the largest consumers, whilst the galvanisers, who have experienced quiet conditions, have been unable to give much support to the spelter market. Considerable interest was taken in the meeting of the Continental Spelter Cartel, which took place on December 11th. It had been anticipated that a curtailment of production would be decided upon to bring it more into line with the demand. It was also understood that a proposal would be discussed for making the penalties for over-production by members of the Cartel much heavier than at present. Apparently, these measures did not receive the necessary support, and it was decided to leave the present arrangements unchanged until July 31st, 1934. The somewhat ineffective result of the meeting did not influence the market a great deal, although prices dropped slightly. Fresh arrivals of metal are expected from Germany this month, and this has had a rather adverse effect upon the position, although, of course, the metal itself will go into bonded warehouse. The American statistics give the stocks at the end of November as 101,000 tons, an increase of 5860 tons over the October total. The production was 32,900 tons, compared with 35,100 tons in October, whilst the deliveries dropped to 27,000 tons, against 38,200 tons in the previous month.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Craftsmanship.

A sign of the importance attached to a decentralisation of industry was afforded by the inauguration in Paris last week by the President of the Republic of a huge reinforced concrete and steel building covering 32,280 square feet, known as the Cité Artisanale Clémental, containing 430 workshops, with areas ranging from 130 to 860 square feet, and each supplied with water, gas, electricity for power and light, compressed air, central heating, and telephone. There is a spacious sales hall, as well as postal and despatch services, and everything to make the building self-contained. The Cité Artisanale lies in a district where small craftsmen have for generations crowded together in buildings with rooms fitted up as workshops, with machines driven from shafts taking power from an engine, usually installed in the basement. These men are expert mechanics who prefer to be independent, and the work done by them is of a high quality, and the cost is low because there are practically no overhead charges. Many of these insalubrious collective workshops are doomed to demolition, and the Cité Artisanale Clémental marks a new departure in providing men with workshops where they can carry on their trades under favourable conditions, and may become owners of the shops after paying rent for a certain number of years. It has another significance in showing what is being accomplished by the Confédération Générale de l'Artisanat Français in organising small craftsmen all over the country. Expert workers generally prefer to be their own masters rather than be wage earners in big factories. There are no recent figures of the number of workshops and factories in France, but those for 1921 gave a total of 1,433,000, comprising 958,251, with men working on their own account by themselves or with one assistant, 321,497 with two to five helpers, and 25,217 employing six to ten men. No one employing more than ten men is included in the category of master artisans. These small workshops, of course, cover every branch of industry, and the proportion of master mechanics and those engaged in metal working of all kinds is quite large. In view of the enormous preponderance of small producers, the Confédération Générale de l'Artisanat Français has definite views upon the part they will play in industrial reorganisation. The President, Monsieur Tailledet, believes that the restrictions imposed by foreign markets will seriously affect the situation of factories running on lines of mass production, and that more importance will consequently be given to the small artisan class. He affirms that about 80 per cent. of the production of small workshops in the Paris district and practically the whole of the production in the provinces consists of essentially French luxury goods for export. This dependence upon a foreign demand does not apply so much to the metal-working industry, except art metal goods and fittings. Seeing that more than a million master artisans are declared to be working mainly for export, and are consequently suffering from the restrictions imposed by foreign markets, there appears to be some ground for the fear of exporting industries that a continuance of the present trade policy may have the effect of throwing 2,000,000 men out of work. The idea of the Confédération Générale de l'Artisanat is to reverse a policy which is mainly guided by particular interests, and to organise the artisan community in a way to make it a power in the land and develop a movement for trade facilities in co-operation with similar artisan federations in other countries. In Germany the movement is said to be particularly strong. There is nothing subversive in the French programme. Instead of concentrating effort on big factories for the production of certain classes of goods, which, it is affirmed, can be produced more satisfactorily by individual skill than by mass methods, the object of the artisanal movement is to save skilled workmen from what is declared to be the servitude of the machine; to regard the machine as the servant of the man and not as a primary means of production in which the man loses his skill and individuality; to group master craftsmen for the sale of their goods direct to consumers and to promote the training of skilled workers from the constantly swelling ranks of young men who study for engineering and other professional degrees with little prospect of ever being able to make a living. There is a tendency to return to the old system of trade guilds, which has, in fact, grown notably during the past few years, and it is believed that this decentralisation of industry will give it stability, and that by international co-operation there will be an adjustment of exchanges which will avoid risk of massive unemployment amongst skilled men in the future. This movement does not, of course, encroach on engineering trades in which the independent master craftsman can play little part, except as a supplier to big firms, but it indicates a growing tendency on the Continent to decentralise lighter industries in which native artistry, initiative, and skill are required to maintain a high standard of quality.

Engineers' Degrees.

There is at present before the Senate the Bill for giving a legal status to engineers which was passed by the Chamber of Deputies and repudiated by engineering societies and institutions on the ground that it aimed at legalising a state of things that could not be allowed to continue. Amongst other strongly criticised provisions, the Bill recognised degrees granted by private correspondence schools, and the measure was intended, in fact, to democratise the profession by offering facilities for obtaining degrees. It is now being examined by a Commission of the Senate, which has suppressed the clause recognising diplomas granted by correspondence schools, and it is to be replaced by another clause making the conditions for obtaining degrees much more stringent.

Shipping.

The total tonnage of ships laid up in French ports on October 15th last was 846,233, a reduction of 93,914 tons as compared with the returns six weeks previously. In this total there were twenty-three passenger steamers, amounting to 173,794 tons, and 232 cargo ships, of an aggregate tonnage of 639,934. The reduced tonnage of ships laid up has followed upon the reorganisation of the shipping services and the putting of ships in commission.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

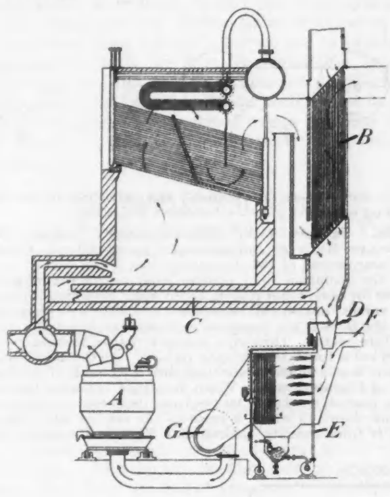
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

400,881. June 10th, 1933.—Gas-fired Boilers, Babcock and Wilcox, Ltd., Farringdon-street, London, E.C.4.

This boiler is fired with gas from the producer A. It is aimed to provide a uniform quality of gas and prevent the formation of clinker. In the uptake of the boiler there is an air preheater B. The heated air is delivered partly by the duct C to the combustion chamber of the boiler and partly by the duct D to the humidifier E. This air is mixed with fresh cold air from the inlet F and is forced into the producer by the fan G. It will be observed that waste heat is used to supply the vapour necessary for the working of the producer, so that the boiler is relieved of the necessity of producing that much steam.—*November 2nd*, 1933.

N°400.88ı

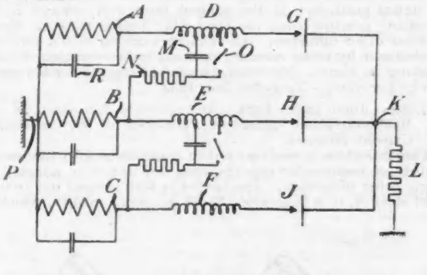


TRANSFORMERS AND CONVERTERS.

400,634. January 22nd, 1932.—Electric Converting Apparatus, Dr.-Ing. Erwin Marx, of 3, Rankestrasse, Braunschweig, Germany.

In accordance with this invention a rectifier with spark gaps is used for rectifying H.T. polyphase current. Connected to the phases A, B, and C of the three-phase transformer are the choke coils D E F, which are connected to three rectifying spark gaps G, H, and J of the plate-point type. Conductors are carried from these spark gaps to the D.C. conductor K to which is connected the D.C. load represented as a pure resistance L. When both positive and negative half-waves of an A.C. voltage are rectified, and when a considerable capacity is available between the continuous current line and earth, it is advisable not to connect the zero point P to earth. The undulation of the continuous current voltage to earth will then be very slight, more particularly in the case of an uneven number of phases of the transformer. The ignition of the spark gaps is effected in accordance with the invention by means of an auxiliary voltage. The current circuits for generating this auxiliary voltage are shown in the phases A and B. The capacity M is charged through the protective resistance N. O is a mechanical interrupter of the spark jump type, which causes the condenser to discharge across a portion of the series inductance E at the instant at which ignition is desired. The consequent oscillation produces at the gap G a high voltage which ignites the arc. The oscillation is kept away from the transformer by the capacity R and the resistance N prevents the occurrence of an interphase short circuit. The theory of the apparatus is explained.—*October 23rd*, 1933.

N°400.634

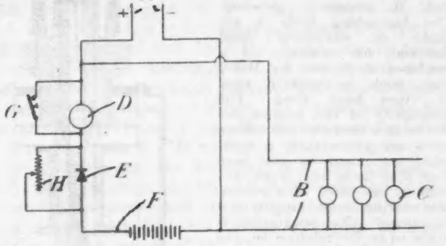


BATTERIES AND ACCUMULATORS.

400,246. April 18th, 1932.—Control of the Flow of Current in Electric Circuits, Thomas Frederick Edwin Watson, and the Westinghouse Brake and Saxby Signal Company, Ltd., both of 82, York-road, King's Cross, London, N.1.

This invention is particularly applicable to the charging and discharging circuits of secondary batteries in which for many purposes it is desired to limit the charging rate to a definite value, which may be relatively low, as in the case of trickle charging, while permitting a discharging rate which is unlimited or relatively high. The positive and negative circuit conductors of a source of direct current are indicated at A, the conductors being directly connected to conductors B connected to a load C, which is thus directly supplied with current from the supply conductors. The positive conductor is also connected in series with an ammeter D and a dry surface contact rectifier E to the positive terminal F of a secondary battery, the negative terminal of which is connected to the negative supply. The rectifier E is so connected in circuit that charging current supplied from the supply conductors to the battery traverses the rectifier E in its reverse or high resistance direction, an adjustable resistance H being connected in shunt to the rectifier. A switch G is provided for short-circuiting the ammeter D, this switch being normally closed and being adapted to be manually opened when it is desired to measure the current traversing the rectifier E. The operation of the apparatus is as follows:—Under normal conditions the load C is supplied with current directly from the supply conductors, while the battery is at the same time being trickle charged by current supplied from the conductors A through the closed switch G, the rectifier E, and the resistance H. The magnitude of this charging current is partly dependent upon the reverse direction resistance of the rectifier E, and partly on the value of the variable resistance H, the actual charging current supplied to the battery being indicated when desired by opening the switch G, so as to cause this current to traverse the ammeter. In the event of failure in the supply of current from the conductors A the battery will supply current to the load circuit conductors B, and it will be observed that this current will traverse the rectifier E in its normal or low resistance direction, so that flow of current to the load C from the battery will be relatively unimpeded.—*October 18th*, 1933.

N°400,246

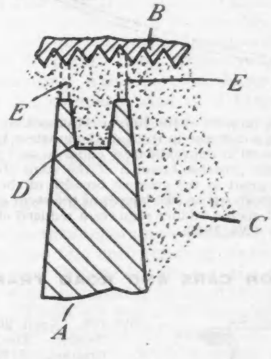


TRANSMISSION OF POWER.

400,882. June 10th, 1933.—Centrifugal Clutches, Pulvis Aktiengesellschaft, Glarus, Switzerland.

In those forms of centrifugal clutch in which the torque is transmitted from the driving part A to the driven part B by the resistance of a granular mass of material C, it is, naturally, essential that the moving part should be strong enough to resist the rotary thrust of the granular material. The result is that with ordinary constructions the moving part is so thick that a hard mass of the material builds up round the periphery of the rotor and makes the operation of the clutch harsh. As a consequence the inventors cut a groove D in the periphery of the driver and claim that then the compacting effect is only produced between the narrow limits of the broken lines shown at E E.—*November 2nd*, 1933.

N°400,882

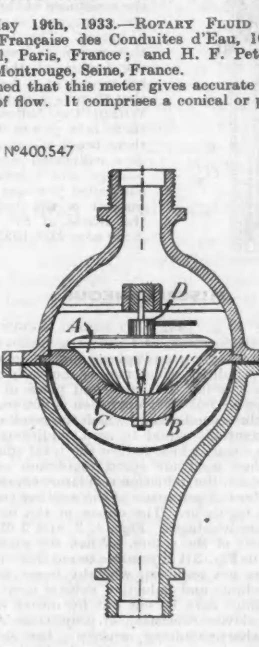


MEASURING AND TESTING INSTRUMENTS.

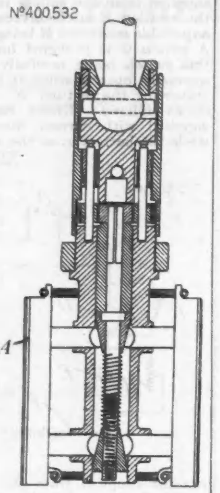
400,547. May 19th, 1933.—Rotary Fluid Meters, Compagnie Française des Conduites d'Eau, 106–108, Rue de Lourmel, Paris, France; and H. F. Petot, 11, Passage Morel, Montrouge, Seine, France.

It is claimed that this meter gives accurate readings over a wide range of flow. It comprises a conical or paraboloid rotor A placed in a correspondingly shaped bowl B. This bowl is perforated with tangential nozzles C, which direct the water on to the rotor. The rotor is free to rise and fall and takes up a position appropriate to the amount of water passing. It drives a counting mechanism D.—*October 26th*, 1933.

N°400.547



MACHINE TOOLS AND SHOP APPLIANCES.



Nº400532

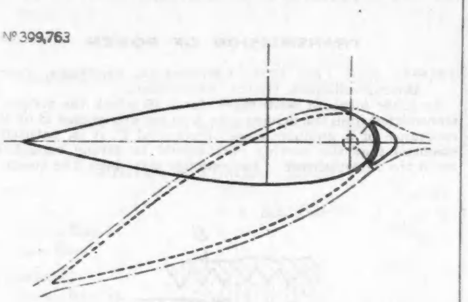
400,532. April 25th, 1933.—Finishing Cylinder Bores, E. Ryser, 7, Rue Hubner, Mulhouse, Haut - Rhin, France.

For the purposes of finishing the bores of, for instance, internal combustion engines, the surface is burnished by means of a tool such as that illustrated. The bore is, of course, first prepared by machining and, if necessary, grinding. The burnishing tools A are made of extremely hard material, for example, of a hardness of 90 deg. by Moh's scale, such as tungsten steel or other hard steel. The peculiarity of the process lies in the fact that the burnishing tools are given such a rapid axial movement in the bore that they make only from one-fifth to one-third of a revolution during each longitudinal movement. No suggestion is made as to the relative lengths of the tools and the bore to be burnished.—*October 26th*, 1933.

SHIPS AND BOATS.

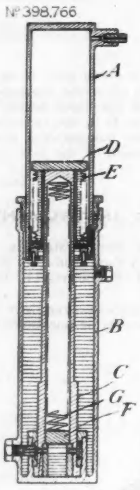
399,763. June 10th, 1933.—Rudders, Deutsche Schiff-und Maschinenbau Aktiengesellschaft, Bremen, Germany, and F. Schleufe, Wesermünde-Geestemünde, Germany.

Claim is made for: "A steering rudder having a fixed rudder stem, of which the complete cross section is of curved symmetrical water-cutting form, the greatest breadth of the rudder cross section projecting beyond the greatest breadth of the stem cross section, and the pivotal axis being at a distance in front of the greatest breadth of the rudder cross section, in which the pivotal axis is a distance in front of the greatest breadth of the rudder cross section approximately equal to said greatest cross section and the greatest breadth of the stem cross section is about half as great as the greatest breadth of the rudder cross section, but greater than the length of the stem cross section." It is said that such a rudder requires a reduced effort to put it over.—*October 12th*, 1933.



Nº399,763

MOTOR CARS AND ROAD TRAFFIC.



Nº398,766

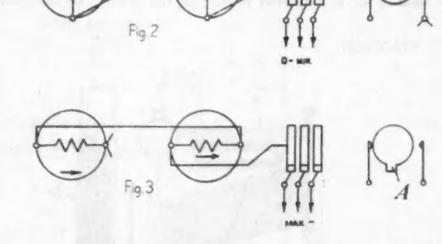
398,766. April 20th, 1933.—Shock Absorbers, M. Charles, 217, Boulevard Saint-Denis, Courbevoie, Seine Department, France.

It is suggested that this shock absorber may be also used as a carrying spring. The load is applied between the two telescopic parts A and B. Within the lower part B there is a hollow piston-rod C, carrying a piston D, which, with the assistance of the compressed air entrapped above, acts as a spring. The lower face of this piston is connected with the bottom of the cylinder A by means of a bellows E, so that there is a fluid-tight joint. Within the hollow piston-rod there is a piston F, on which there bears a spring G. There is a calibrated communicating passage, and a series of valve-controlled passages between the interior of the bellows E and the inside of the casing B.—*September 21st*, 1933.

MISCELLANEOUS.

400,714. June 14th, 1932.—Universal Induction Regulators, Josef Sousedík, of Vsetín, Czechoslovakia.

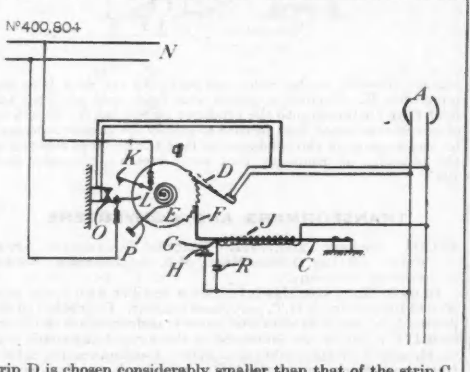
Induction regulators for multiphase currents comprising two stator and rotor windings, which may be mutually displaced and which serve for varying the value and phase of the induced voltage, are known; but their operation is not economical. In the position of the secondaries in which the resultant secondary voltage is substantially equal to zero, additional ohmic and inductive losses occur, which reduce the total efficiency of the apparatus. When used for speed regulation of multiphase commutator motors, the induction regulators employed hitherto do not provide for compensation of the wattless current in each position of the regulator. The object of the invention is to remove these disadvantages. Figs. 1, 2, and 3 illustrate three different positions of the rotors. When the rotors are in the position shown in Fig. 2 it is possible to cut out the rotor windings, as they are not required, whereby losses which may be caused by the ohmic and inductive voltage drop are avoided. The rotor windings may be cut out by means of a slip ring short-circuiting device consisting of projections A on the slip rings and by short-circuiting brushes. The short-circuiting position of the slip rings is shown in Fig. 2. In the third position—Fig. 3—the induced voltages of the rotors are added together, but as in this position the currents flow in the opposite direction to that indicated in Fig. 1, the resulting value is a minus quantity. For the purpose of adjustment of the phase displacement one of the stators B C is mounted so that it can be turned, and, if necessary, it is also connected by means of a suitable mechanical gear with the rotors in order to adjust the phase displacement, as is, for instance, desirable in the speed regulation of commutator motors for obtaining any particular power factor, including a leading phase.—*November 2nd*, 1933.



Nº400,714

400,804. January 11th, 1933.—Electric Thermal Time-delay Relays, *International General Electric Company, Incorporated, of* 120, *Broadway, New York, U.S.A.*

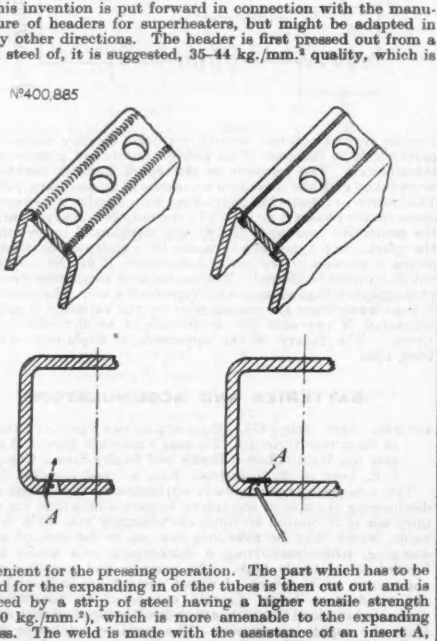
By the operation of a control relay on the occurrence of a fault or for some other reason, and if some switching process has to be carried out on this occurrence and after a certain lapse of time, the lines A are energised and thus the bimetallic strips C and D are heated. The strip C moves upwards, moving the wheel E forward a tooth through the pawl F. At the same time the contacts G and H are opened and thus the circuit of the heating winding J is interrupted. When the strip C is heated the strip D is also heated, so that it moves from its dotted position to the position shown in which it rests on the ratchet wheel and prevents it from running backwards. The time constant of the strip D is chosen considerably smaller than that of the strip C, so that its first switching stroke can be utilised. After a certain number of operations of the strip C contact K meets contact L and thus closes the working circuit N, which causes the operation of a signal or the carrying out of switching processes. By the interruption of the contacts O the heating current of strip D is interrupted. As soon as the latter has cooled down sufficiently to free the ratchet wheel and the pawl F has moved back into its initial position the spring P can move the wheel E back into its initial position. If the control relay still remains in its operating position then the time-relay begins to work afresh without other influence. An efficient working of the contacts is obtained by using mercury contacts or interruption devices working in vacuo. Moreover, parallel connected condensers R can be provided.—*November 2nd*, 1933.



Nº400,804

400,885. June 16th, 1933.—Autogenous Welding, N. V. Machinerieen-en Apparaten Fabrieken, of 30, Croeselaan, Utrecht, Holland.

This invention is put forward in connection with the manufacture of headers for superheaters, but might be adapted in many other directions. The header is first pressed out from a mild steel of, it is suggested, 35–44 kg./mm.^{2} quality, which is convenient for the pressing operation. The part which has to be drilled for the expanding in of the tubes is then cut out and is replaced by a strip of steel having a higher tensile strength (41–50 kg./mm.^{2}), which is more amenable to the expanding process. The weld is made with the assistance of an insert A, which is tacked in position and holds the welding metal in place during the work.—*November 2nd*, 1933.



Nº400,885

Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

A Seven-Day Journal

◆

Fire Protection in Cross-Channel Ships.

ON Tuesday, December 19th, the 400ft. turbine-driven cross-Channel steamer "Princess Maud," designed by William Denny and Brothers, Ltd., was successfully launched at Dumbarton, the naming ceremony being performed by Lady Craigavon, wife of the Premier of Northern Ireland. The new steamer will be used on the L.M.S. Larne-Stranraer service and is designed to carry some 1250 passengers. It is noteworthy that all her cabin accommodation, public rooms, corridors, &c., are protected against fire by an equipment which has been designed and installed by the patentees, Mather and Platt, Ltd., of Manchester. It comprises about 400 Quartzoid bulb sprinklers, divided into four installations, each installation having its own controlling valves and automatic alarm. Fixed in the chart room is an indicator, which, upon the sounding of an automatic alarm, shows the particular section that has been brought into operation. Although the "Princess Maud" is the first British-built vessel to be so protected, it may be recalled that in 1914 Mather and Platt installed "Grinnell" sprinklers in certain parts of the two German-built vessels, the "Imperator" and the "Vaterland," now the "Berengaria" and the "Leviathan," respectively, and that these partial equipments are still in good order and operative in the event of fire.

The Late Mr. D. M. Shannon.

IT is with deep regret that we have to record the death, at the comparatively early age of fifty-one, of Mr. David McCrorie Shannon, a well-known personality in the marine oil engine industry. Mr. Shannon received his early training with Vickers Ltd. at Barrow-in-Furness and for some years was attached to the firm's oil engine department. Shortly after the outbreak of war he joined Cammell Laird and Co., Ltd., of Birkenhead, and as head of the oil engine department was responsible for the design and construction of the Camellaird-Fullagar opposed-piston two-stroke oil engine, which was subsequently fitted to many ships and applied for land work. In 1926 Mr. Shannon joined the Fiat Company and was responsible for the introduction of the Fiat oil engine into Great Britain and the establishment of Fiat British Auxiliaries, Ltd. Quite recently Mr. Shannon designed a successful oil fuel lubricating oil filter called the "Rotoklene" strainer, which we have described. After a short time with the Newbury Diesel Company, Ltd., of Newbury, Mr. Shannon took up an appointment as sales engineer with the "R.N." Diesel Engine Company, Ltd., of Altrincham and London, in whose service he was at the time of his death. He had many friends in the marine oil engine industry, and his untimely death shortly before he was to have been married will be widely regretted, both in this country and abroad.

The Use of Coal at Sea.

AT a meeting of the Marine Fuel Committee of the Coal Utilisation Council, which was held on Wednesday, December 13th, problems attending the use of solid fuel in sea-going vessels were exhaustively examined, and it was decided that in the near future steps should be taken to increase the consumption of coal at sea in opposition to the use of imported oil fuels. To achieve this end, it was decided to set up two sub-committees not too large to be effective, which will report to the main committee. One of these committees will consider the specification and supply of coal for marine purposes, while the other will be entrusted with the task of dealing with up-to-date plants for the efficient utilisation of coal at sea. The committees will make their recommendations at an early date. The Marine Fuel Committee is a representative body of shipowners, colliery owners, research officers, marine engineers, and superintending engineers, from among whom the following members have been chosen for the two sub-committees above referred to. The members of the Fuel Committee are: Messrs. J. Harrison, W. J. Drummond, H. H. Merrett, R. Addy, Edward W. Green, J. Johnson, T. F. Hurley, Leighton Seagar, S. Gill; and those of the Machinery Committee, Mr. A. E. Laslett, Engineer Rear-Admiral W. M. Whayman, Mr. R. J. Walker, Engineer Captain Dunlop, and Mr. J. Johnson.

National Certificates and Diplomas in Mechanical Engineering.

As briefly mentioned at the meeting of the Institution of Mechanical Engineers, held on Friday evening, December 15th, Lord Irwin, the President of the Board of Education, recently received the President of the Institution, Mr. Alan Chorlton, and several others closely associated with the National Certificates scheme, notably Dr. H. S. Hele-Shaw, F.R.S., Past-president, who has been Chairman of the Joint Committee from its inception until the present time. Lord Irwin expressed the opinion which is widely held in the world of technical education, that the national certificate schemes as a whole are proving one of the most valuable educational developments since the war. He recognised the value of a painstaking and detailed administration which is the only means by which initial vision can be turned into a well-ordered, trusted, and popular national institution. Time has shown that the original conception of the national certificates and diplomas contained this element of vision, and he noted that in that matter the Institution of Mechanical Engineers was first in the field, and that the scheme with which it is associated is still the largest. He believes that among many of the best of those who have not had the opportunity of a university education, no need is more deeply felt than for some means to acquire the sense of status in their chosen profession, such as nationally attested qualifications based upon educational attainments, together with industrial experience, can effectively confer. For such students the national certificate schemes have, for the first time, offered the opportunity they desired, and it is probably to this that their great and deserved popularity is mainly to be attributed. It may be added that similar schemes are in operation in conjunction with the Scottish Education Department, and the Ministry of Education in Northern Ireland, and that in other fields besides mechanical engineering similar co-operation exists between other professional institutions and these Government Departments.

The New Orient Liner.

THE new Orient liner to be built by Vickers-Armstrongs, Ltd., which was briefly referred to in one of last week's Journal notes, will have a distinctive appearance, as she will only have one funnel and one mast, whereas the other ships in the Orient Line fleet all have two funnels and two masts. The change has been rendered possible by the introduction of water-tube boilers which has made it possible to do away with one set of uptakes. The propelling machinery will comprise a twin-screw arrangement of geared turbines, taking steam from oil-fired water-tube boilers, and designed to give an output of about 24,000 shaft horse-power. The speed of the new ship will be greater than that of the "Orontes," which is 20 knots. The length of the new liner will be 665ft., which is more than that of existing vessels of the fleet, while her beam has been increased in order to provide for substantially larger cabins. She will be designed to carry 475 first-class, and, instead of third-class, 675 tourist class passengers. A feature of the accommodation will be the larger number of single-berth cabins and an increased number of private bathrooms. The games deck, always one of the principal features of Orient liners, will, in the absence of a second funnel, be large and exceptionally free from encumbrances.

The Late Mr. S. E. Saunders.

BY the death of Mr. Samuel Edward Saunders, which took place in the Isle of Wight on Sunday, December 17th, Great Britain has lost a leading designer and builder of racing motor boats. Mr. Saunders, who was president of Saunders-Roe, Ltd., and was seventy-seven years of age, began business at Goring-on-Thames, but moved his works to East Cowes in the Isle of Wight, where many noteworthy racing boats were built and lifeboats constructed for the Royal National Lifeboat Institution. Two of the most famous racers were the "Ursula," a 50ft. boat built for the Duke of Westminster, which for four successive years won nearly every Monte Carlo event; and "Mapleleaf the Fourth," constructed for Sir E. Mackay Edgar, which in 1912 won back the Harmsworth International Trophy from America and successfully defended it in the Solent the following year. Shortly before the war Mr. Saunders took up the construction of flying boats, and in conjunction with Mr. Tom Sopwith designed and built what was stated to be the first amphibian flying boat. It carried off the Mortimer Singer prize of £500 for seven consecutive landings on land and sea. Mr. Saunders introduced sewn plywood construction for use in his racing craft and flying boats. He was a member of the Institution of Naval Architects and of the Royal Motor Yacht Club and the Royal London Yacht Club. He held a Royal warrant as motor yacht builder to the King and was a well-known figure during Cowes week.

Fuel Oil for Central Heating.

AN interesting demonstration of oil-fired central heating plant took place at the end of last week in the Glasgow offices of Scottish Oils and Shell-Mex, Ltd. The plant, which has been recently installed, comprises automatic burners designed to utilise a heavy grade of oil fuel with thermostatic temperature control. In emphasising the importance of oil-fired central heating to Scotland, Mr. G. P. Laidlaw, the manager, pointed out that in the Scottish shale oil industry over 4000 men were employed in the shale fields alone, irrespective of those employed in marketing, distribution and the allied industries. Mr. N. L. Hudson, of London, said that there were now in operation in this country between 9000 and 10,000 fuel oil burners, of which about 700 were in Scotland. The first completely automatic oil burners were those introduced from America about six years ago, but such burners had suffered almost total eclipse in face of those designed by British firms. Among the most successful of such firms were the Clyde Oil Fuel System, Ltd., of Glasgow and London, and Laidlaw, Drew and Co., Ltd., of Edinburgh, which companies had developed oil fuel burning equipment which allowed the heavier grades of oil fuel to be used without loss of efficiency and with a saving of approximately 20s. per ton compared with other fuels.

The Late Mr. G. J. Churchward.

THERE is not a railway man who will not hear with profound regret of the tragic death of Mr. G. J. Churchward, who for many years was locomotive superintendent of the G.W.Ry., and the designer of many notable locomotives. A few years after the war, Mr. Churchward retired, but he continued to live in the company's house. It stands beside the line at Swindon, and it was Mr. Churchward's habit to cross the rails to the works in which he still took a lively interest. On Tuesday last, his mutilated body was found on the line after the passage of the Fishguard express, and it is supposed that, owing to a slight mist and his failing eyesight, he miscalculated the speed of the approaching train. We shall publish a memoir of his life and work in our next issue.

John Brown and Co., Ltd.

ON Wednesday of last week, December 13th, the announcement was made that Lord Aberconway, who, for the past twenty-seven years, has been the chairman of John Brown and Co., Ltd., shipbuilders and colliery proprietors, has, on grounds of health, retired from that position. He will be succeeded by his eldest son, the Hon. Henry McLaren, the deputy chairman of the company, who, for some time past, has taken a leading part in the activities of his firm and has now been appointed its chairman. Lord Aberconway, who was born in 1850, and is now, therefore, in his eighty-third year, is also chairman of numerous iron, coal, steel, and other industrial companies. He is a Vice-president of the Federation of British Industries. The new chairman, the Hon. Henry McLaren, is chairman of Thomas Firth and John Brown, Ltd., deputy chairman of the Tredegar Iron and Coal Company, Ltd., and a member of the board of Dorman, Long and Co., Ltd., and several other companies. In his long period of office, Lord Aberconway has seen many outstanding warships and liners built and engined by his company, and it is fitting that his son's succession in the leadership of his firm should coincide with the promise of an early resumption of work on the new Cunarder.

A Large Palestine Water Scheme.

FURTHER particulars are now available with regard to the steel pipe line and pumping stations recently ordered by the Crown Agents for the Colonies in connection with the scheme for supplying Jerusalem with water. There are about 31 miles of 18in. steel pipes, and four pumping stations, with a reservoir at each station. From the Ras-el-Ain springs the pipe line will follow the railway to Lludd and from that point the road from Jaffa to Jerusalem. As recently recorded in our Market Notes and News, the contract for the pipe line has been placed with Stewarts and Lloyds, Ltd., and will be probably executed at the firm's Airdrie works. The oil engines will comprise twelve medium-speed vertical oil engines, each of 350 B.H.P., using heavy fuel oil, and will be built by the National Gas and Oil Engine Company, Ltd., of Ashton-under-Lyne. Each engine will drive a seven-stage centrifugal pump, and the pumping plant will be supplied by the Harland Engineering Company, Ltd. The scheme is to be proceeded with immediately, and it is understood that the construction will be in the hands of the Public Works Department, under the direction of Mr. Fawcett Pudsey, the Director of Public Works in Palestine.

A Brazilian Naval Training Ship.

THE launch of the Brazilian naval training ship, "Almirante Saldanha," from the Barrow shipyard of Vickers-Armstrongs, Ltd., on Tuesday, December 19th, was noteworthy, not only for the interesting character of the vessel, but on account of the fact that it was the first launch from the Barrow-in-Furness shipyard made since September, 1932. The launching and naming ceremony was performed by Madame Regis de Oliveira, the wife of the Brazilian Ambassador, who represented Madame Getulio Vargas, the wife of the President of Brazil. The "Almirante Saldanha" is a four-masted sailing ship, equipped with oil engines for auxiliary propelling and lighting purposes. Her total sail area will be about 27,000 square feet, and her engines have a total of 1400 B.H.P. She has a length of 262ft. 6in., a breadth moulded of 52ft., and a depth of 28ft. 6in., with a measurement of about 2500 gross tons. Speaking at the luncheon following the launch, Sir Herbert Lawrence stated that the contract for the vessel had been obtained at a higher price than those quoted by other countries, but there were other factors besides price. The ship is the first of nine vessels now in various states of construction at Barrow and awaiting launching, and the keel of the new Orient liner will be laid early next year.

A.C. Voltage Regulators.

No. V.

(Continued from page 603, December 15th.)

APART from the more or less recent introduction of several types of A.C. regulators mainly for use on low-pressure distribution systems, progress is still being made in the design of on-load tap-changing gear for attachment to transformers with capacities up to the largest required. A new equipment of this kind, known as type V X C O, has been introduced by the Hackbridge Electric Construction Company, Ltd., of Walton-on-Thames. Smooth and continuous pressure variation is obtained with no disturbance of the line conditions, and with no continuous magnetising loss or change of phase displacement. All switching operations are performed by cam-operated contactors, which give a rapid break. The maximum current broken is merely the magnetising current of a special intermediate regulator, which is connected between two adjacent tappings during the short period of each change. The lower limit of transformer size to which the apparatus can be economically applied, is largely a matter of relative cost. For transformers below about 1500 kVA another equipment* is manufactured giving a smooth variation at a cost in keeping with that of relatively small transformers. The principle of connecting a regulator across the tappings when making a voltage change is not, of course, new. One of the early tap-changing transformers built by the Hackbridge Company† had an intermediate regulator, but the present equipment is designed on different lines.

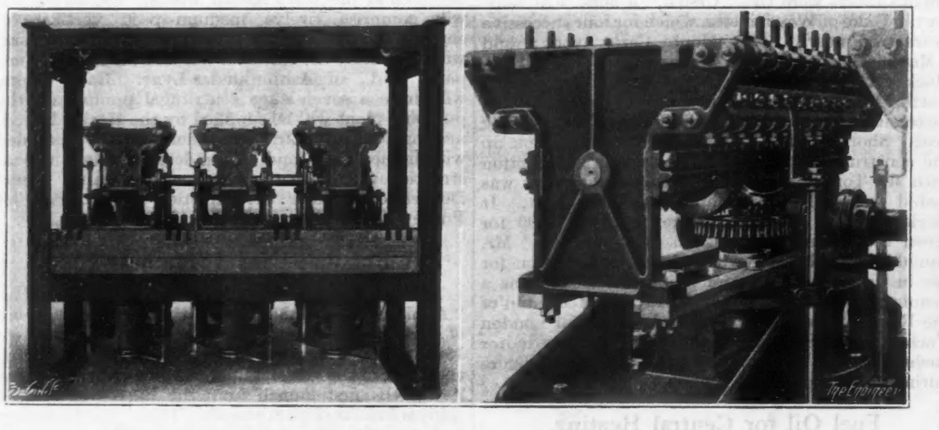
FIGS. 49 AND 50—CONNECTIONS FOR ON-LOAD TAP-CHANGING EQUIPMENT WITH A REGULATOR BETWEEN TAPPINGS



FIGS. 51 AND 52—THREE-PHASE, TAP-CHANGING EQUIPMENT AND DRIVING GEAR

The intermediate regulator which is brought into operation during each tap change in the equipment under consideration resembles an induction regulator with a wound rotor and stator. One end of the stator winding is connected through a slip-ring to the mid-point of the rotor winding, and the other end to the main transformer winding. The ends of the rotor winding are connected *viâ* slip rings through switchgear to adjacent tappings on the transformer winding, as shown in Fig. 49 (*a*), in which for the sake of clarity winding III. is shown as the moving element, although in practice A B moves in relation to III., which is stationary. The regulator is wound, so that if the rotor is in the position in which section I. of the rotor winding is in the maximum and section II. in the minimum relationship to the stator III., position C′ in Fig. 49, the fluxes in I. and III. are opposed, while those in the windings II. and III. are additive. Consequently in this position the reactance and therefore the voltage between A and C will be zero, and between B and C a maximum. Similarly, if the rotor is turned so that winding II. is in the maximum relationship and winding I. in the minimum relationship to the stator III., *i.e.*, position C″, Fig. 49, the voltage between B and C will be zero and that between A and C a maximum. Thus by turning the rotor through 180 electrical degrees the voltage of C is varied smoothly from the pressure at one end of the rotor to that at the other end, and since the ends A and B of the rotor winding are connected to adjacent tappings, the rotation of the rotor varies the potential of C from the voltage of one tapping to that of the next. In practice the connections between the ends of the rotor winding A and B and the transformer tappings are made and broken by cam-operated contactors. Two contactors operated in the same way are also employed for short circuiting the regulator windings from C to A or C to B, in order that when the tap change has been completed the transformer load current does flow through the regulator windings.

SEQUENCE OF OPERATION.

The actual circuit of a single-phase equipment is shown in Fig. 49 (*b*). In changing from tapping No. 1 to No. 2, in order to raise the voltage, the sequence of operations is as follows :—Before the change begins the short-circuiting contactor S_1 and tapping contactor 1 will be closed, whilst all other contactors will be open, the regulator position being C′—Fig. 49 (*a*). Tapping contactor No. 2 then closes, thus connecting the regulator across tappings 1 and 2. Next, contactor S_1 opens, but it does not break any current, for with the regulator in the position C′ the point C is at the same potential as A, *i.e.*, the potential of tapping No. 1. The regulator is then turned to the position C″, thus smoothly raising the potential of C to that of B, *i.e.*, to the voltage of tapping No. 2. Contactor S_2 then closes, thereby connecting C directly to tapping No. 2, and diverting the transformer current from the regulator winding. Finally, contactor No. 1 opens and merely breaks the magnetising current of the regulator, since the reactance from C to A is now at a maximum. The tap-changing operation is now complete. A three-phase equipment comprises three identical single-phase units arranged to operate in the manner described, and connected in star, as shown in Fig. 50, or in delta according to requirements. The chart accompanying Fig. 50 shows the complete switching sequence covering the whole range of tappings, the regulator rotating 180 deg. after each operation *b*.

MECHANICAL ARRANGEMENT.

The contactor and regulator assembly is illustrated in Fig. 51, which shows the equipment removed from the tank in which it normally operates, and disconnected electrically from the transformer and mechanically from the operating gear. The latter, which may be motor or hand controlled, is normally coupled to one end of the horizontal main shaft, which couples the three single-phase units for three-phase operation. In each unit both the vertical regulator shaft and the horizontal cam shaft that operates the contactors are driven by a single worm gear on the main shaft, as illustrated in Fig. 52, which shows the driving worm meshing with a worm wheel at the top of the regulator shaft, and also with a worm wheel which drives the contactor cam shaft. As indicated above, the main driving shaft actually consists of three shafts, one serving each phase unit joined together for electrical reasons by insulating sections. On each unit the steel shaft carrying the driving worm runs in two bearings, and is coupled to the adjacent insulating section through a coupling having a reasonable degree of flexibility. The contactor assembly is illustrated in Fig. 53, which is a plan view of this portion of the equipment. The tap-changing contactors are arranged in two rows A A. Along the centre and below the level of the contactors is the square shaft B, rotated by the worm wheel C, which, as explained, is driven by a worm gear on the main shaft. On this square shaft is a cam D, having a spiral contour similar to that of a worm gear, and a bore of square section. Rotation of the shaft therefore causes rotation of the cam which is a sliding fit on the shaft and can therefore move longitudinally. On either side of the cam shaft and level with it are two toothed racks, the teeth of which engage with the convolutions of the cam, as shown diagrammatically in Fig. 54. Consequently, when the

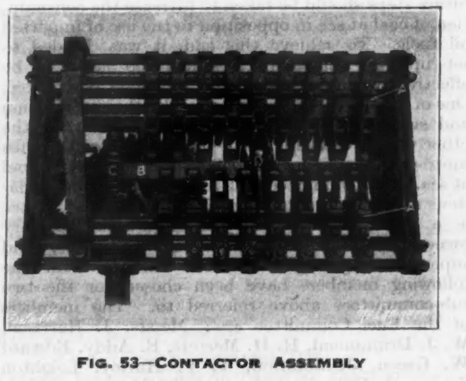


FIG. 53—CONTACTOR ASSEMBLY

---

* See THE ENGINEER, August 11th, 1933.

† See THE ENGINEER, July 12th, 1929.

cam shaft is rotated the cam not only rotates but also moves along the shaft, and as it does so the cam face engages in turn with the rollers at the ends of the arms operating the contactors, which are thus closed, held closed, and opened in the correct sequence. Flicker blades fitted to the "start" and "finish" of the cam contour ensure rapid opening of the contactors. Mounted behind the cam shaft worm wheel, but hidden from view in Fig. 54, are two other contactors operated by simple cams and corresponding to the switches S_1 and S_2 in Fig. 50. From this description it will be clear that when the main shaft of the equipment is rotated, either by hand or motor, the cam shaft of each phase is rotated, thereby operating the necessary contactors to complete the tap change, while at the same time each regulator rotor is turned through the requisite arc, with the result that a smooth stepless voltage variation is obtained between tappings. The framework, Fig. 51, into which the whole of the equipment is built closely fits into the oil-filled boiler plate tank, and with the disconnection of the flexible coupling that joins the end of the main shaft to the external driving gear and the removal of the various tapping connections, the equipment can be lifted straight out of the tank for inspection or other purposes.

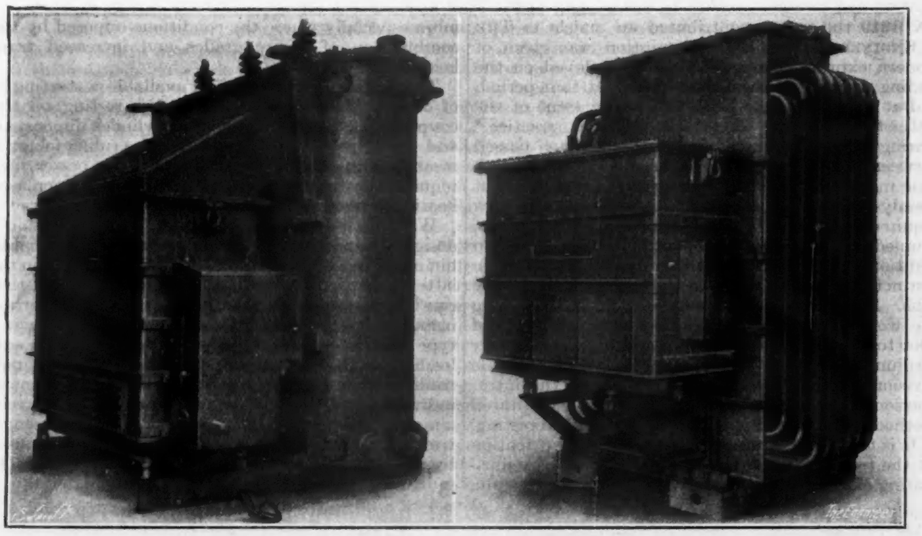
FIG. 54—CAM MECHANISM



FIGS. 55 AND 56—REMOTE AND MANUALLY-CONTROLLED ON-LOAD TAP-CHANGING TRANSFORMERS

When the operating pressure is above approximately 33 kV the three units are insulated from one another and from earth by means of porcelain insulators. Below this pressure the units are mounted on two longitudinal beams of selected and treated wood to be seen in Fig. 51. Between the units the wood is serrated, as shown, to increase the leakage path, and the weight of the equipment is taken by steel angles on which the insulating beams rest. Connections to the regulator rotors are made through slip rings at the bottom of each unit, and inspection doors with bolt-on covers in the tank side facilitate inspection of the brush gear and rings. The mid-point rotor terminal is connected in each case to the regulator carcase, which is insulated from earth and, as stated, from the adjacent units of a three-phase equipment. As is shown in Fig. 52, the studs for connecting the equipment to the transformer tappings are arranged at the top of the contactor assemblies.

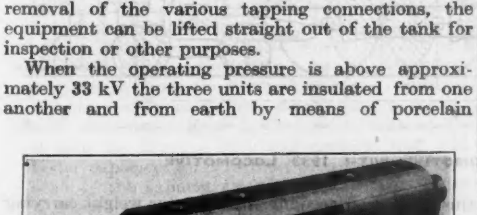


FIG. 57—ROTOR FOR BARBOUR REGULATOR

DRIVE AND CONTROL.

The steel cubicle housing the drive, control, and indicating mechanism is housed outside the tank, as illustrated in Fig. 55, which shows a tap-changing equipment designed for remote or for manual control fitted to a 10,000-kVA three-phase 22/11-kV transformer. For automatic or remote controlled operation this cubicle contains the motor drive together with the motor and auxiliary contactors, indicating and limit switches, &c. For outdoor operation the cubicle is naturally made waterproof. The manually controlled equipment, shown in Fig. 56, is fitted to a 2500-kVA 11/2·1-kV transformer. Motor-operated equipments have the requisite means for hand operation and a simple mechanical interlock prevents motor operation while tap changing by hand. Interlocks also ensure that a motor-driven equipment accurately completes each tap change, while overrun of the mechanism at either end of the tapping range is prevented by separate pairs of limit switches. Various indicators of the multiple lamp or dial patterns are fitted.

The choice of such equipment is largely determined by the distance between the tap-changing gear and the indicating point, the number of pilot wires available, and similar considerations. All equipments, however, are fitted with a mechanically operated indicator similar to that to be seen at the side of the drive and control cubicle in Fig. 55, such indicators being scaled in terms of tapping positions, plus or minus voltage percentages as required. Automatic or remote control generally follows normal practice. Without alteration the control system is suitable for parallel operation of two or more equipments from a common push button control point, the requisite precautions being taken to ensure that under normal conditions the tap changers will all keep in step.

THE BARBOUR REGULATOR.

The Barbour regulator differs from the ordinary induction regulator in that there are no windings on the laminated rotor core, which, as Fig. 57 shows, is more or less rectangular with rounded ends. The stator is, of course, also laminated and it carries both the primary and secondary windings, which are placed in the large slots P P and S S respectively—Fig. 58. As these windings are not distributed in a large number of small slots it is a relatively simple matter to insulate these regulators for high voltages. The makers, the Electrical Apparatus Company, Ltd., of Vauxhall Works, South Lambeth-road, also claim that this arrangement of the windings improves the electrical characteristics and promotes silence. When the rotor of a polyphase regulator of this kind is in the neutral position no voltage is induced in the secondary and there is no phase shift in this position. For a given direction of primary magnetising current, and therefore magnetic flux, the flux in question passes in different directions through the secondary when the rotor is in the alternative positions indicated by the full and dotted lines. The voltage induced in the secondary changes its sign correspondingly. Halfway between these positions the rotor will stand with its ends directly facing the secondary slots and the primary flux will pass partly into the rotor from pole 1 and out at pole 4 and will also pass partly in from pole 2 and out at pole 3. In this mid-position, therefore, none of the primary flux passes through the secondary and consequently no voltage is induced in it. In other intermediate positions, however, a certain amount of flux passes through the secondary, the effect as a whole therefore being that as the rotor is turned from the "full on" position in one direction through 90 deg. to the "full on" position in the other direction the voltage induced in the secondary gradually falls to zero and then rises again with reversed sign.

For remote or fully automatic working two systems of control are employed. On large regulators an auxiliary motor is used with reduction gearing, clutch and lever for emergency hand operation, reversing contactors, brake and a control drum with limit switches and contacts for a remote control indicator, when required. All these items are mounted in a suitable enclosure. For fully automatic working a new and patented voltage relay has been devised, with a thermal element responsive through the intermediary of a potential transformer to the voltage under control.

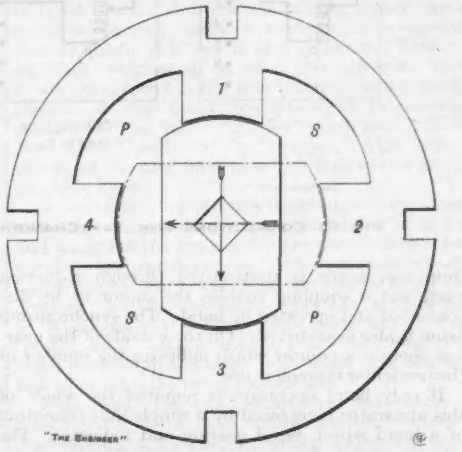

FIG. 58—ROTOR AND STATOR

A typical Barbour regulator removed from its tank is shown in Fig. 59. The upper bearing bracket is integral with the top casting carrying the driving mechanism, terminal chamber and accessories. The rotor, Fig. 57, is built on a central steel plate having bearing journals and a square driving part cast integral with it. On each side of the plate there are laminations and copper plates to control the magnetic flux, the whole being clamped together by means of bolts. There are no slip rings or flexible leads, for the rotor consists solely of steel and copper. The regulators are made for single and three-phase supplies for the voltage regulation of feeders, &c. They are also used in conjunction with on-load tap-changing equipment and as controllers and starters. When used in conjunction with tap-changing equipment, the Barbour regulator gives, as in the case of the Hackbridge apparatus, a gradual change of voltage without shock to the transformer or system.

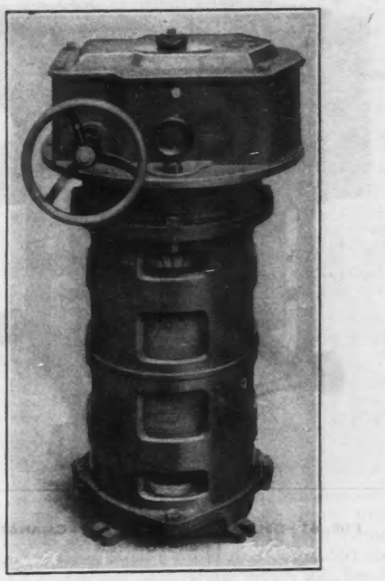

FIG. 59—BARBOUR REGULATOR

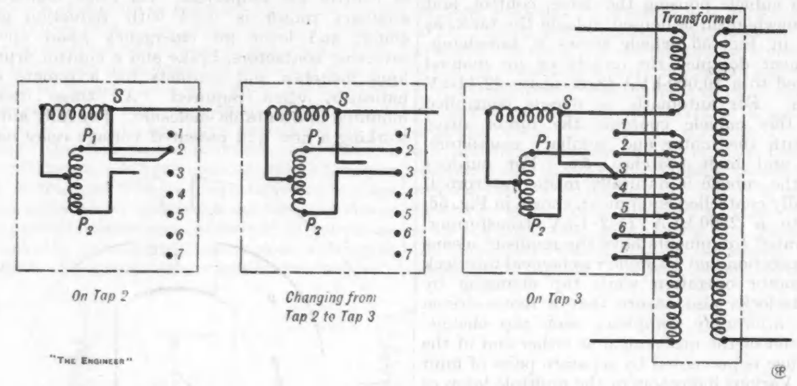
TAP-CHANGING EQUIPMENT WITH BARBOUR REGULATORS.

The Electrical Apparatus Company's on-load tap-changing equipment is contained in an oil-filled casing attached to the tank of the transformer it is desired to control. Enclosed in a waterproof box above this casing is the driving mechanism, which, in the case of automatic control, comprises an electric motor, a pair of interlocked reversing triple-pole contactors for starting and stopping the motor, a drum synchronised with the selector switches, and having segments to prevent over-run, and, if necessary, to give remote indication of the transformer tapping in use. There is also a pair of maintaining switches which, once a tapping change has begun, keeps the motor running independently of any other control until the change is completed and ensures that the selector switches make full contact. Power from the motor is transmitted through reduction gear, and a coupling enables the motor to be disconnected and operated by hand. The synchronising drum is also gear-driven. On the outside of the gear-box there is a pointer which indicates the number of the particular tapping in use.

If only hand operation is required the whole of this apparatus is replaced by a simple unit consisting of a hand wheel, bevel gearing and indicator. The selector switch for each phase consists of a drum controller of standard design, except for the fact that the fingers are mounted on substantial round bakelite tubes without a metal core. Although the method of applying a Barbour regulator to tap-changing equipment is similar to that described, we reproduce the makers' diagram of connections in Fig. 60. In this case, it is to be remembered, there are no slip rings or brushes. The inner end of the secondary winding is permanently connected to the mid-point of the primary P_1 and P_2, while the outer end S of the secondary is permanently connected to that point on the main transformer winding which is to be joined to the various tappings.

When full on a given tapping, the outer secondary end S and one end of the primary are also in connection with the tapping, the other end of the primary being disconnected, as shown on the left of Fig. 60. In changing to the next tapping, say, from 2 to 3, the free end of the primary is first connected to tapping 3, and the point S of the secondary is disconnected from tapping 2 in the manner shown in the centre of the diagram, the rotor of the Barbour controller being in the position in which no voltage is being generated between these points. The effect of disconnection is, therefore, merely to cause the line current to flow through one-half of the primary and through the secondary against their self-impedance. The rotor of the controller is then gradually turned to reverse the controller voltage so as to change the voltage of S from that of the tapping being taken out of service to that of the tapping that is being brought into use.

The point S is then connected to the new tapping as shown on the right of Fig. 60 without involving any change of voltage, but merely cutting out the impedance of the induction controller. At the same time the end of the primary connected to the tapping, from which the transfer has been made, is disconnected. The only switching operations necessary are those for making or breaking the small magnetising current of the Barbour controller and those for connecting or disconnecting two points which, apart from a small amount of self-impedance, are at equal potentials.



On Tap 2

Changing from Tap 2 to Tap 3

On Tap 3

FIG. 60—CONNECTIONS FOR TAP-CHANGING EQUIPMENT WITH BARBOUR REGULATOR

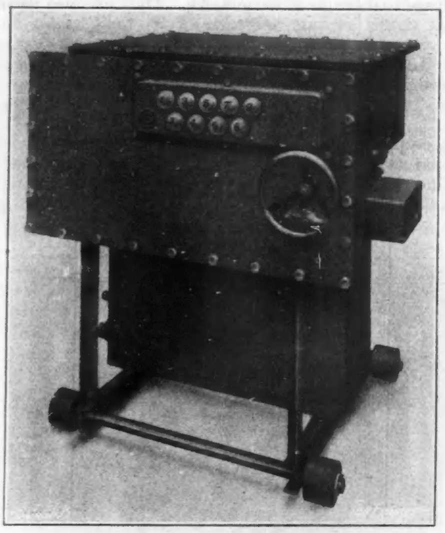


FIG. 61—SMALL ON-LOAD TAP-CHANGING TRANSFORMER

A more simple and less expensive on-load tap-changing equipment built by the Electrical Apparatus Company, Ltd., is shown in Fig. 61. It cannot be made for such large capacities as the apparatus described, and, like most other equipments, it changes the voltage suddenly. Drum controllers make and break circuit without the use of special contactors. The rapid step to step motion is under the control of a spring, which is wound up while the controllers are held fixed, while, on the release of the controllers the spring throws them to the next position, where they are again held fixed. On alternate steps connection is made direct to a transformer tapping, while on intermediate steps an auxiliary auto-transformer is connected to adjacent tappings and current is led out from the mid-point of the auto-transformer, which provides a step between the tappings in the well-known way. Hand or motor operation may be arranged for, with provision for emergency hand operation in the latter case, and, if necessary, a relay is supplied for fully automatic control.

Equipments of medium size, can readily be attached to one side of the transformer by means of a flange surrounding a plate through which the leads from the transformer are to be brought. The transformer in the case of equipments of smaller capacities—Fig. 61—is conveniently mounted inside the same casing below the selector switches. This forms a convenient unit, which, besides having many applications as a step-down transformer with regulation, may be supplied as a voltage regulator in places in which no transformation of the rated voltage is necessary. The transformer itself then takes the form of an auto-transformer having a capacity corresponding to the boost required.

(*To be continued.*)

Recent American Express Locomotives.

By E. C. POULTNEY.

No. I.

IN 1919 the writer contributed an article to THE ENGINEER in which a description was given of modern express passenger engines employed on the leading railways of the United States at that period, and at the same time he briefly noted some of the distinctive features found in American practice.* During the intervening years which have passed between the date of the earlier review and the present time many changes have taken place, brought about mainly by demands for greatly increased power now required to handle heavier trains at high speeds, coupled with improved operating efficiency. In addition there has during more recent years been a distinct tendency to augment the length of locomotive runs. In order to satisfy such requirements involving the working of passenger trains weighing upward of 1000 tons behind the tender either at high speeds over medium-grade lines, or unaided over heavy grade divisions at lower mean speeds, has caused the introduction of engines of high power and necessitated methods of construction both novel and interesting.

It is the writer's present purpose to draw attention to the trend of modern American practice by illustrating examples which typify recent designs covering the six-coupled and eight-coupled types, as now used on some of the principal railway systems.

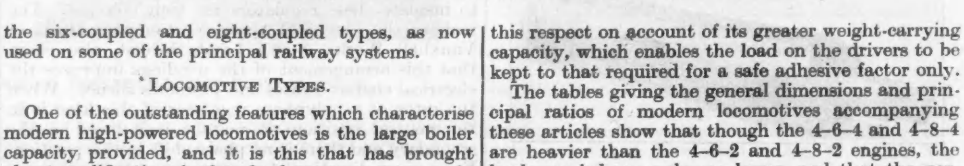

FIG. 1—COMPARISON OF 1893 LOCOMOTIVE WITH 1933 LOCOMOTIVE

LOCOMOTIVE TYPES.

One of the outstanding features which characterise modern high-powered locomotives is the large boiler capacity provided, and it is this that has brought about modifications in the wheel arrangements now in evidence, compared with the prevailing practice at the time the earlier review was written. Formerly the majority of locomotives built for fast passenger services were of the "Pacific" type, having the 4–6–2 wheel formation, but the same reasons which made it necessary in the earlier stages of development to change from the 4–4–0 to the "Atlantic," and from that to the "Pacific," have in turn led to a modification of the latter, and produced the 4–6–4 arrangement, while at the same time the "Mountain" or 4–8–2 is giving place to the 4–8–4 type now found, more especially where the conditions imposed by the combination of heavy grades and increased train loads are to be met.

The maximum tractive effort available at starting is, of course, governed by the weight resting on the coupled axles, together with the cylinder dimensions and steam pressure, but at speed the ruling factor is steam production, and to maintain the power now required has necessitated the provision of increased heating surfaces and larger grates.

With both the "Pacific" and the "Mountain" designs, considerable heating surface is attainable, but in the matter of fire-box and grate area, and in the latter in particular, the limit is set by the weight that can be supported by the trailing truck. In certain instances very powerful engines of the "Pacific" type may be employed, owing to high allowable axle loading for the coupled axles, thus relieving the single trailing axle; but this is not always so, and in general individual weights on the coupled axles do not exceed a maximum of 70,000 lb., especially for fast passenger traffic, because of the increased rail loading caused by the dynamic augment at high speeds. The four-wheeled trailing truck has helped materially in this respect on account of its greater weight-carrying capacity, which enables the load on the drivers to be kept to that required for a safe adhesive factor only.

The tables giving the general dimensions and principal ratios of modern locomotives accompanying these articles show that though the 4–6–4 and 4–8–4 are heavier than the 4–6–2 and 4–8–2 engines, the loads carried per axle are lower, and that the percentage of the engine weight carried by the driving wheels is not so high, but at the same time an adequate adhesive factor is maintained.

When considering these features, and especially when comparing the relative tractive efforts, it will be seen that the tractive effort of the 4–6–4 and 4–8–4 engines is not greater than for the 4–6–2 and 4–8–2 designs, but the increased boiler capacity enables these engines to generate much more power at high speeds, and, as will later be shown, it is now possible to develop 1000 I.H.P. per coupled axle.

In carrying further a comparative study of these locomotive types it will be seen that the four-wheeled trailer has made it possible to provide grate areas proportionate to the larger heating surfaces, that the engine weight per square foot of combined heating surface is generally rather lower for the modified "Pacific" and "Mountain" designs, and further, more heating surface is provided in relation to the cylinder power, as shown by the boiler demand factors. This increase in heating surface in proportion to the cylinder capacity, together with the larger grates made possible by the introduction of the four-wheeled trailing truck, are directly responsible for the high sustained powers developed by modern 4–6–4 and 4–8–4 engines.

---

BOILERS AND SUPERHEATERS.

Beyond an increase in size, boiler construction has not changed materially, though the higher working steam pressures now general have directed attention to the use of special steels with weight reduction as an object.

Usually, the fire-box is formed with a combustion chamber extending forward into the barrel section, and Nicholson thermal syphons are very frequently applied, both in the fire-box itself, where they form a support for the arch, and in the combustion chamber.

One constructional feature of interest is the now very usual practice of welding together all the plates for the internal fire-box and for the combustion chamber. The tubes and flues are also welded into the rear tube sheet.

All locomotives, as a matter of course, use superheated steam, and whereas formerly the type A equipment was commonly employed, the type E superheater is now very largely used. This superheater has much larger heating surfaces and, moreover, forms a greater proportion of the boiler, for, compared with the type A with a heating surface equal to about 20 per cent. of the total combined, this figure for the E type superheater is about 30 per cent. In addition to the large heating surface, the flues housing the elements make up a greater part of the total free area through the boiler, which are therefore exposed to a larger proportion of the heat liberated by the fire-box. The use of this superheater has considerably increased the amount of superheat and improved cylinder efficiency and the power output.

Feed-water heating is receiving much attention, and, in general, all the most recent locomotives are fitted with feed heaters of the closed or open types, complete with pumps.† The exhaust steam injector has also been fitted to some extent; that used is known as the Elesco pattern, which is a modification of the Metcalf design. The Sellars injector is also used, but so far as the writer is aware, the feed-water heater with pump, the latter either of the reciprocating or rotary (turbine-driven) description, is much the most common. Feed heating with exhaust steam is held to improve fuel performance, and add to boiler capacity, and, further, as about 12 or 15 per cent. of the exhaust steam from the main cylinders is recovered for feed purposes, the equivalent of added tank capacity is obtained.

An examination of modern engines shows that there is a tendency to fit the regulator or throttle valve in the smoke-box where it can be arranged between the superheater and the steam chests. This permits the auxiliaries, including the air compressors, feed pumps, and the booster and stoker engine to use superheated steam, whilst, as steam is always in the elements, they are protected against overheating when the throttle is closed. Furthermore, dampers, which would be inconvenient to fit in conjunction with the type E superheater, are unnecessary. For the purpose of isolating the superheater from the boiler, a shut-off valve is usually fitted to the steam pipe in the dome.

There is a decided tendency towards higher working steam pressures which range between the limits of 200 lb. and 275 lb. per square inch, while, experimentally, pressures of as much as 300 lb. have been tried in the normal type of boiler. Generally, however, pressures of 225 lb. or 250 lb. are found, and the Pennsylvania, after employing as standard for many years a pressure of 205 lb. has adopted 250 lb. for its most recent designs. The Chicago and North-Western has in service a number of very large 4–8–4 passenger engines operating at this figure, but the boilers and machinery are so constructed that the pressure may be raised to 275 lb. if required.

CYLINDERS, MAIN FRAMES, AND RUNNING GEAR.

The high power of modern engines has prompted considerable development work in the construction of the main framing to stand the stresses set up by the necessarily high piston loads, and the desire to reduce weight has been a further factor which has been instrumental in modifying the design and construction of both the cylinders and frames. Cast steel has been very largely introduced for cylinders, which are either cast with the half-saddle in this material, or in pairs in one piece with the saddle and valve chests complete. This type of construction has been used in conjunction with the usual separate frames with cross bracing members of cast steel, but the latest engines now have the whole of the main framing, including the cradle for the fire-box support and the cylinders, complete with piston valve chests, smoke-box saddle, and front bumper beam, with all brackets, made in one solid casting. In certain instances, the hind cylinder covers and the reservoirs for the air brake, have also been included, these being arranged between the side members and in the centre of the engine. Some of these locomotive bed frames have reached large proportions; for instance, those for some heavy 4–8–4 engines for the Chicago and North-Western weigh as much as 72,500 lb., or, say, 33 tons of 2240 lb. Cast steel cylinders are lighter than cast iron, but are, of course, fitted with iron liners, as are also the piston valve chests.

As is well known, the two-cylinder engine is, for all practical purposes, universal in American practice, and all the designs now under notice are of this description. To obtain the high powers necessary, the cylinders must be of considerable size, and the diameters range generally between 25in. and as much as 30in., with, consequently, high piston loads to be transmitted through the motion and framing. In considering this, it must, however, be remembered that the bar type of main frame, when compared with that of plate construction, is particularly well adapted to meet the stresses imposed, and makes it possible to provide an adequate support for the axle-boxes, as the centre of the boxes and the journal bearings can coincide with the centre line of the side members of the main frames. So far as motion parts are concerned, alloy steels are frequently used, and the older strap form of big end for the connecting-rods is giving place to a solid end fitted, as a rule, with floating bushes, which are also often applied to the side rod pins.

In order to reduce reciprocating weights, crosshead design is receiving attention, and the Laird type is much used. Another underhung design having multiple bearing surfaces working in a specially formed single slide bar is also common. This construction originated on the Pennsylvania, where it was introduced in the first place for heavy freight engines, its use being now extended to passenger engines of the later "K. 4's" and new "K. 5" and "M 1" and "M 1 *a*" classes. This type of crosshead has also been fitted by Baldwin to engines for other lines.‡

On account of the stresses imposed, and the weight to be carried, journal bearings must be of large size, and those for the main axles are always larger than for the other coupled axles. Axles are usually hollow bored, and so are crank pins, the weight being thus reduced; but the practice is especially useful where, as is generally the case, these parts are of heat-treated steel. Main driving boxes are now often fitted with supplementary adjustable side bearings, as well as with the usual crown brass.

While the one-piece locomotive bed frame is, possibly, one of the most notable features of modern construction, a further interesting innovation is the growing use of roller bearings, more especially for tender and engine trucks, though experiments are being made now with roller bearings on the coupled axles. Machine friction will be reduced by this form of journal bearing, but reduced maintenance costs and increased availability are the primary considerations.

TENDERS.

The large engines now in use naturally require considerable supplies of fuel and water; consequently, large tenders are provided. Fuel space has increased from about 12 tons to as much as 28 or more in certain instances, and in like manner the amount of water carried has risen from 8000 to over 22,000 gallons, U.S. measures in both instances. The use of these large tenders has eliminated special stops for re-fuelling and taking water, and has been a factor in enabling the extension of locomotive runs, and has, therefore, played an important part in reducing operating costs.

Examples of very large tenders as applied to fast passenger locomotives are to be found on the New York Central, where those fitted to the "Hudson" class have a loaded weight of 302,700 lb., the fuel carried being 28 tons, 56,000 lb., and the tank capacity 14,000 gallons, whereas the standard "Pacifics" of 1920 had tenders of 168,000 lb. weight, when loaded with 8000 gallons of water and 12 tons of coal.

On the Pennsylvania the latest K. 5 "Pacifics" have tenders carrying 35,600 lb. of coal and 14,000 gallons of water, and a full weight of 244,900 lb., while the "M. 1 *a*" 4–8–2 engines have tenders turning the scale at no less than 378,360 lb., or

---

† More than 90 per cent. of the new locomotives built in 1930 were fitted with feed water heaters.

‡ For a description see THE ENGINEER, May 15th, 1925, page 551.

168 long tons, which can carry 63,000 lb. of coal, and 22,000 gallons of water.

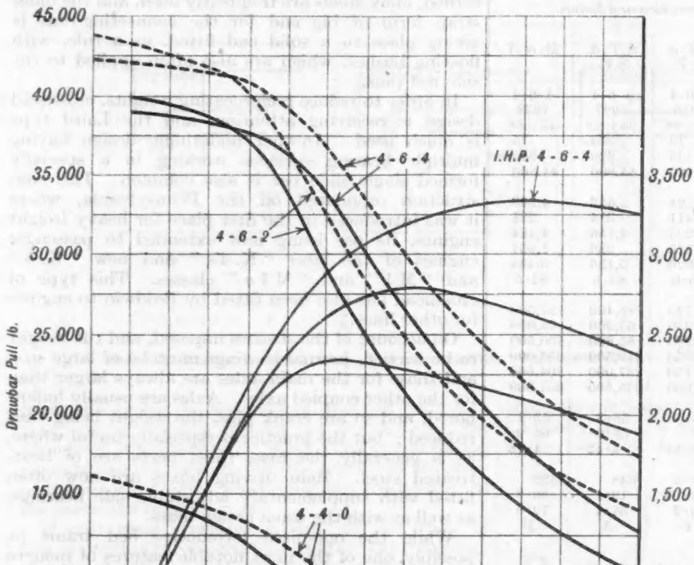

Fig. 2—Characteristics of 4-4-0, 4-6-2, and 4-6-4 Engines

The construction of these high-capacity tenders has been greatly facilitated by the development made in the design of the underframing, which now takes the form of a single steel casting, which makes at the same time a bottom for the tank. This has proved a very strong structure, necessary when it is considered that the length between the truck centres may be as much as 32ft., and the total length of the tank 48ft. or more. The tender sides are either riveted to the frames or welded, and often the whole upper part is welded together throughout, which makes a satisfactory construction, being strong and free from leakage; further, a neat finish is readily obtained. Tender trucks are of cast steel, frequently of the six-wheeled type. Rolled steel solid wheels, 33in. diameter, are practically standard, with journals of about 6½in. by 12in.

Increase in Size and Power.

Before describing representative examples of modern high-speed passenger locomotives, which have been selected for treatment, it will be of interest to note the increase in size of engines of this type. Fig. 1 shows to the same scale the N.Y.C. engine No. 999, built by Buchanan in 1892 and exhibited at the World's Fair in 1893, and a modern 4–6–4 "Hudson" type locomotive as now in use on the New York Central lines. The 4–4–0 or "American" type engine is superimposed on the 4–6–4, thus bringing out clearly the increase in size that has taken place during the last forty years of development, and it will be noted that the new engine is as large as the entire locomotive of 1892, including the tender. The comparative size of these engines as thus illustrated will be of further interest when reference is made to the next diagram, Fig. 2, in which the pull, speed, and horse-power are plotted for the 4–4–0 engine, a representative "Pacific" of 1918, and for the 4–6–4 "Hudson" of the present day. The leading dimensions and other data appertaining to these engines are given in Table III.

Table III.—*Comparative Particulars of Express Locomotives.*

Engine	124,000	306,000	352,000
On drivers	84,000	197,000	187,000
Tender	80,000	194,200	302,700
Total, locomotive	204,000	500,200	654,700
Superheat, deg. Fah.	—	200	250
Draw-bar pull at 60 m.p.h., lb. ..	2,988	12,616	15,997
Draw-bar horse-power at 60 m.p.h.	476	2,020	2,550
Heating surface per D.B.H.P. at 60 m.p.h.	4·03	2·32	2·52
Loco. weight, lb. per D.B.H.P. at 60 m.p.h.	427	247	256
Engine weight, lb. per sq. ft. total heating surface	64·5	65·0	54·6
Superheater type	—	A	E
Feed water heater	—	No	Yes
Tank capacity, galls, U.S.	3,587	10,000	14,000
Coal, lb.	13,800	32,000	56,000

Referring to the graph, the full lines represent the pull available at the rear of the tenders between 10 and 70 miles per hour, and the broken lines the indicated tractive effort at the cylinders. The D.B.H.P. curves are also shown for the three engines, and for the 4–6–4 the I.H.P. curve is plotted as well. In the lower part of the diagram are shown by the lines sloping upwards to the right the resistance offered by the trains. The upper curve relates to a modern passenger train of 1000 tons made up of 75-ton coaches, and the lower to the Empire State Express of 1892 made up of 35-ton cars and having a weight of 200 tons behind the tender.

Referring to the tabulated statement, it will be noted that the heating surface per D.B.H.P. at 60 m.p.h. has fallen from 4·03 square feet in 1893 to 2·52 square feet in 1927, the date when the first of the 4–6–4 engines was introduced, and that the locomotive weight per D.B.H.P. developed at 60 m.p.h. has during this period been reduced from 427 lb. to 256 lb. A similar comparison can also be made between the standard "Pacific" of 1918 and the 4–6–4, where it will be seen that although the latter engine has a tender weighing 302,700 lb., as against 194,200 lb. in the case of the "Pacific," representing an increase of 55 per cent., the locomotive weight is only 256 lb., D.B.H.P., equal to an as against 247 lb., per increase of 3·5 per cent.

If we now compare these engines on the basis of engine weight only—that is, comparing the weight of the actual power plant with the D.B.H.P. or net power available—the following figures are found:—

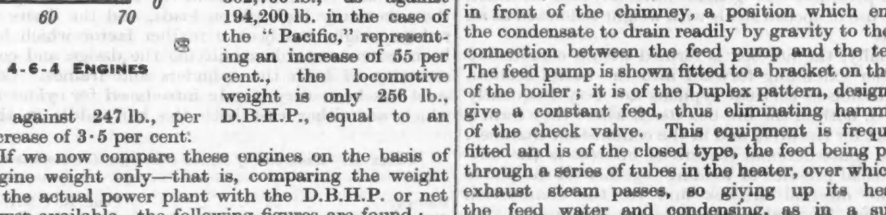
	4–4–0.		4–6–2.		4–6–4.
Engine weight per D.B.H.P., lb.	840	..	151	..	138
Weight on drivers per D.B.H.P. lb.	176	..	97·7	..	73·6

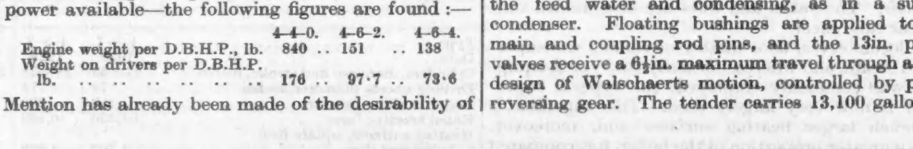
Mention has already been made of the desirability of restricting the weight carried by the driving axles, and in regard to this the improvement made in the power output in relation to the adhesive weight is of interest. Referring to the cylinder power developed per coupled axles, the I.H.P. curve for the 4–6–4 shows that at 60 m.p.h. the indicated horse-power reaches just over 3300, or more than 1100 I.H.P. per axle.

The data just discussed show the improvement in the power weight ratio, both in respect to engine weight and to that carried on the driving wheels when the adhesive factors are practically equal, and the horse-power curves indicate how, for a given rated tractive effort the actual power available at high speed has been increased. As bearing on this latter point it is interesting to quote from the *Railway Mechanical Engineer*, February, 1933, which made the following statement:—"The combination of the large fire-box, the type E superheater, and the four-wheeled trailing truck has converted the locomotive from a machine rated by its starting tractive force to one which is rated by its horse-power capacity," a statement which adequately sums up the ideas underlying modern locomotive design.

Locomotives of the 4–6–2 and 4–6–4 Types.

In the foregoing notes the writer has made no attempt to do more than outline the salient features of modern express locomotives, it being only desired to draw attention to certain constructional and other features, and it is now proposed to supplement the remarks already made by offering some descriptive notes relative to recent designs, supported by illustrations. The engines will be mentioned in the order in which they appear in the tables of dimensions. The first—Fig. 3—locomotive represents the latest "Pacific," as built by the Baldwin Locomotive Works, for service on the Central Railroad of New Jersey (C.R.R. of N.J.). Actually, these engines have been built to work fast and medium speed trains when the stops are frequent, and a high tractive effort is required for rapid starting. They follow in general design a number previously placed in traffic, but have smaller wheels, and an increased boiler pressure, so, though the cylinders are of equal size, the higher rated tractive effort of 52,189 lb. is obtained, compared with 46,841 lb. for those having the larger, 79in., wheels. The superheater is of the A type, but is of large size, having forty elements and 1000 square feet of heating surface, or 27 per cent. of the total combined surface. The fire-box has a combustion chamber, and the distance over the tube plates is 18ft. 8in. The 207 tubes are 2in. and the forty flues 5⅜in. diameter. A feed-water heater of the "Elesco" type is fitted, which is, as shown, mounted on the smoke-box in front of the chimney, a position which enables the condensate to drain readily by gravity to the feed connection between the feed pump and the tender. The feed pump is shown fitted to a bracket on the side of the boiler; it is of the Duplex pattern, designed to give a constant feed, thus eliminating hammering of the check valve. This equipment is frequently fitted and is of the closed type, the feed being passed through a series of tubes in the heater, over which the exhaust steam passes, so giving up its heat to the feed water and condensing, as in a surface condenser. Floating bushings are applied to the main and coupling rod pins, and the 13in. piston valves receive a 6½in. maximum travel through a light design of Walschaerts motion, controlled by power reversing gear. The tender carries 13,100 gallons of water, and 15 tons of coal, and has a cast steel water bottom underframe to which the side sheets are welded; all the internal bracing is also welded to the side sheets. A mechanical stoker is provided and three Nicholson syphons are fitted. The trailing truck is of the usual single-axle type, with cast steel





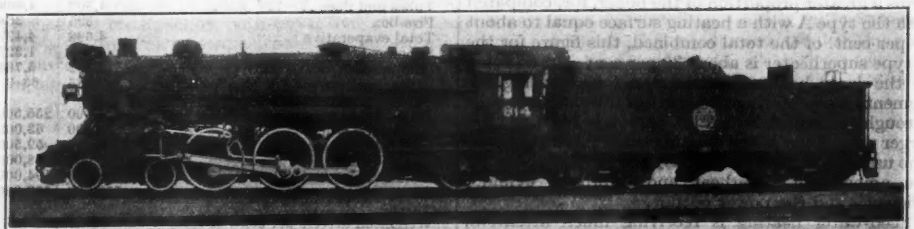


Fig. 3 (Above)—C.R. of N.J. 4-6-2 Type Locomotive
Fig. 4 (Centre)—B. and O. "President" Class 4-6-2 Type Locomotive
Fig. 5 (Below)—P.R. Class K. 5 4-6-2 Type Locomotive

framing. This design of truck is roughly triangular in plan and swings from a centre just behind the trailing axle, and the weight is taken at this point and also at the two hind corners under the rear of the fire-box. The springs are overhung and are compensated with those for the trailing coupled axle through compensating beams fulcrumed in the truck frames. In conformity with usual practice, the Westinghouse air brake acts on the coupled wheels and on the tender.

The Baltimore and Ohio (B. and O.) utilise the class of engine shown by the next illustration—Fig. 4—to work the more important express trains between Jersey City (New York) and Philadelphia, Washington, St. Louis, and Chicago. These locomotives, known as the "President" type, have been built by Baldwin to meet the requirements of Mr. G. H. Emerson, Chief of Motive Power, and are amongst the most powerful "Pacifics" running, having a tractive effort of 50,000 lb., rendered possible by the high axle loading allowable. The weight on the drivers is 201,000 lb., or 67,000 lb. per axle, equal to 29·9 long tons. The boiler is of the usual radial stayed round top type, and the fire-box has a combustion chamber, and two syphons, whilst two arch tubes support the arch. The length over the tube sheets is 19ft., and there are 212 2¼in. tubes, and forty 5½in. flues for the type A superheater. The water spacing round the foundation ring is of ample size, being 6in. at the front and 5in. at the sides and back. These engines are fired by a mechanical stoker, the operating engine being on the tender. The connecting-rod big ends have floating bushes, which are also applied to the side rod pins. The main driving axle journals are 12½in. by 13in., and those for the other coupled axles are 11in. by 13in. long. Walschaerts gear operates 14in. piston valves, having a 7in. full gear travel, 1⅛in. lap, and ¼in. inside clearance. A power reversing gear is fitted. A forced feed lubricator supplies oil to the cylinders, valves, stoker engine, and air brake compressor. The tenders have a one-piece cast steel under frame and carry 17½ tons of coal, and 11,000 gallons of water; they run on eight wheels, and a water scoop is applied, operated by a 12in. air cylinder.

It may here be mentioned that the B. and O., the C.R.R. of N.J., the Pennsylvania, and the New York Central, are the only lines using track troughs.

The New York and St. Louis fast trains weigh up to 940 tons, and the New York Washington expresses to about 526 tons behind the tender, the journey between the latter points of 226 miles being made in 4 h. 45 min. with eight stops.

The principal fast passenger services on the Pennsylvania (P.R.) are handled by engines of the "Pacific" type, the latest example of which is shown by the photograph reproduced in Fig. 5. This locomotive has been designed and built at Altoona Pa, by Mr. F. W. Hankins, Assistant Vice-president in charge of operation. In general, the design follows closely the "Pacific" Class K. 4's, first built in 1914 by the late Mr. J. T. Wallis, but some important modifications have been introduced, which bring them into line with modern practice. The boiler in respect to overall dimensions is the same as for the class "K. 4's" engines, and in construction also follows Altoona practice; but the material used is now a nickel steel for the barrel, and for the combined throat and bottom half of the rear barrel section. The material has a tensile strength of 75,000 lb., comparing with 60,000 lb. for carbon steel plates. The nickel content is specified to be within the limits of 2·75 to 3·25 per cent. The minimum ultimate tensile strength is 70,000 lb., and the yield point 0·5 of this figure.

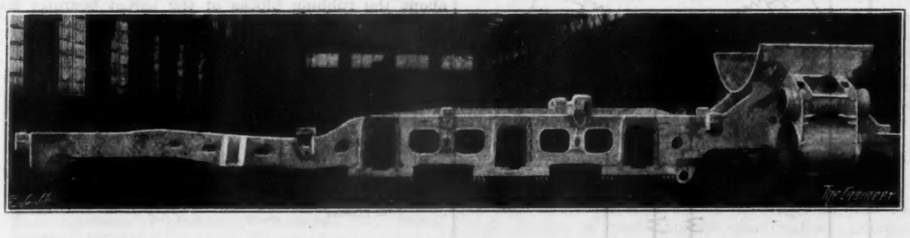

FIG. 6—CAST STEEL FRAME P.R. CLASS K 5 LOCOMOTIVE

The type A superheater of forty elements originally employed has given place to one of the type E with side headers. There are 170 3½in. flues, and ninety 2¼in. tubes, the length between the tube plates is 19ft., as for the earlier engines. The fire-box, with combustion chamber, is as before, and the grate area of 69·89 square feet is also retained. The changes made in the superheater and tubes have resulted in an increase in the total heating surface of 18·75 per cent., but the engine weight is increased by only 3·2 per cent. A further important modification is the use of a one-piece cast steel engine bed frame, which includes in one unit the framing, with all brackets, the cylinders with valve casings, and the saddle. This casting, an illustration of which is reproduced in Fig. 6, was made by the General Steel Castings Corporation. The cylinders are 27in. by 30in., and steam distribution is effected by 12in. piston valves set to give a full gear cut-off of 70 per cent., and operated by a light design of Walschaerts motion, which is controlled by a power reversing gear. The working steam pressure is 250 lb. per square inch. A feed-water heater is fitted. It is of the Worthington S type. The heater or mixing chamber is placed over the smoke-box behind the chimney, where it can be readily connected to the exhaust passages. Cold water is delivered to the mixing chamber by a rotary pump, driven by a steam turbine assembled complete as a unit, and fixed under the footplate. The hot feed is supplied to the boiler by a horizontal reciprocating pump mounted on the left-hand side of the engine at the front end. There is an automatic control for the feed obtained by slowing down the pump when the throttle is closed or only slightly open, as when "drifting." The feed water temperatures vary from 210 deg. to 230 deg. Fah., and higher temperatures are not desired, as the blast pipe and chimney have been specially designed with the idea of reducing back pressure on the pistons. The superheater delivers steam at temperatures of between 700 deg. and 750 deg. Fah. The motion parts are of light design and the crossheads of the multi-bearing pattern. The main rods have floating bushes at the crank pin ends, and the coupling rod pins are similarly fitted. The trailing truck is of the single-axle type standard on the Pennsylvania, and the weight, instead of being taken at the hind corners and pivot centre, is borne by the frame side members through combined sliding and spherical bearings abutting on the underside brackets cast on the main frames. The leading end of the truck frame connects through suitable links with the bearing springs for the trailing coupled axle. It will thus be seen that the truck framing serves also as a compensating connection. The spring compensation is continuous from the leading drivers to the trailing truck. The tenders are of novel design, especially so far as the under framing is concerned, which is a single steel casting, but without side sills. The draw gear pocket at each end are cast integral, and at the bogie centres side bearer arms project outwards to support the tank, which is strongly braced internally in such a manner as to transfer all strains to the centre member of the frame. The tender, which is fitted with a water scoop, carries 14,000 gallons of water, and 16 tons of coal; it runs on eight wheels and weighs, loaded, 245,000 lb.

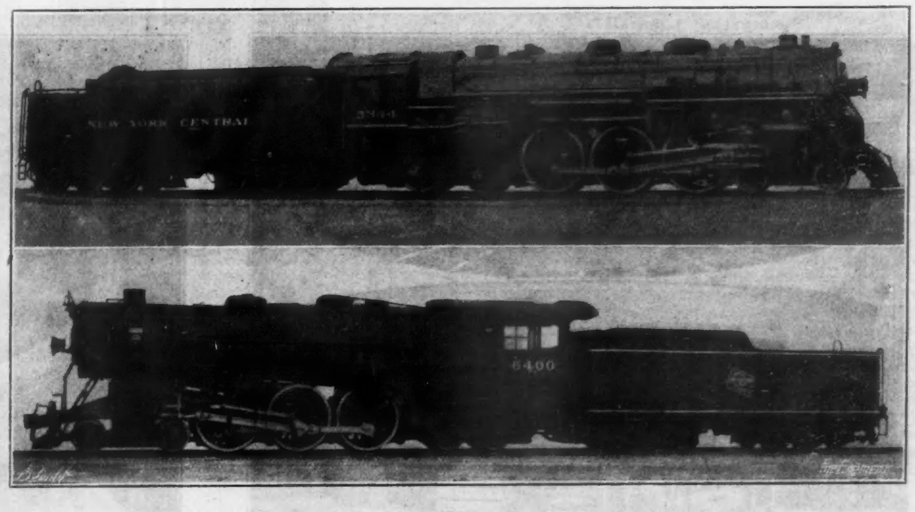

FIG. 7 (ABOVE)—N.Y.C. "HUDSON" TYPE 4-6-4 LOCOMOTIVE

FIG. 8 (BELOW)—C.M. ST. P. AND P. 4-6-4 TYPE LOCOMOTIVE

The following short tabulation compares the previous "K 4's" and the present "K 5" locomotives:—

Class.	K 4's.	K 5.
Cylinders	27 × 28	27 × 30
Drivers, dia., in.	80	80
Steam press.	205	250
Tractive effort, lb.	44,460	54,675
Total heating surface, sq. ft.	4,984	5,919
Grate area, sq. ft.	69·18	69·89
Weight on drivers, lb.	201,830	207,600
,, of engine	308,890	318,700

The New York Central (N.Y.C.) employs 4–6–4 engines of the "Hudson" type for working all important express services, and as this design has already been fully described by the writer in THE ENGINEER, extended reference will be unnecessary.*

The illustration Fig. 7 shows one of the latest of these locomotives to be put into traffic, which, like the others, has been built by the American Locomotive Company. This particular engine, No. 5344, is of interest, because it is equipped with Timkin roller bearings on the leading truck journals, the coupled axles and the tender trucks. The trailing four-wheeled truck has ordinary bearings. An exactly similar locomotive, No. 5343, is fitted in the same manner with S.K.F. bearings. Both were put into service late in 1931, and up to January 1st, 1933 No. 5344 had run 158,300 miles, and 5343 had covered 160,700 miles with satisfactory results. The trains hauled by engines of this type are amongst the heaviest and fastest in the country, and on many of the services the length of individual engine runs has been much extended. In this connection it will be of interest to note that the 20th Century Limited, running between New York and Chicago, a distance of 962 miles, is now operated by two engines only, compared with seven required in 1918. The steam locomotive replaces the electric at Harmon, 33 miles out of New York, and works through to Cleveland, 588 miles, where a change is made, the second engine running the remaining 341 miles to Chicago. The load to-day is fifteen Pullmans, as against ten in 1918.

The Chicago, Milwaukee, St Paul and Pacific (C.M. and St. P.) engine next illustrated—Fig. 8—represents one of fourteen passenger engines built by Baldwin and completed in 1930. From the particulars given in the table it will be gathered that these locomotives are of considerable power. In respect to boiler capacity they resemble the New York Central "Hudsons," but the tractive effort is rather greater, the cylinders being 1in. larger in diameter. The fire-box is fitted with a combustion chamber and there are three syphons, two in the box and one in the chamber. There are 182 3½in. flues for the E type superheater, and fifty-eight 2¼in. tubes, and over the tube sheets the length is 19ft. A mechanical stoker is provided. Boiler feed is taken through a Coffin feed-water heater, the heater portion of which is fitted into the upper part of the smoke-box just ahead of the chimney. These locomotives have a one-piece cast steel frame, complete with cylinders and saddle. Roller bearings are applied to the wheels for the trailing truck. The Baker gear operates 14in. piston valves and reversal is by means of a power control. The revolving, and 50 per cent. of the reciprocating, weights are balanced. The tender runs on twelve wheels, and carries 20 tons of coal and 15,000 gallons of water. The air brake acts on the tender; the air pressure is furnished by an 8½in. cross-compound compressor.

The (B. and A.) Boston and Albany 4–6–4 engines mentioned in the table are generally similar to the "Hudsons" of the N.Y.C., of which system the B. and A. is part. They differ in having smaller drivers and in respect to the working steam pressure, which is 250 lb. per square inch. The full gear cut-off is 65 per cent.

(To be continued.)

IN the course of a paper presented at a meeting of the American Institute of Mining and Metallurgical Engineers, held in New York recently, Mr. L. L. Wyman stated that (1) neither pure copper when oxidised, or deoxidised, nor tough-pitch copper containing up to 0·06 per cent. oxygen is embrittled by hydrogen at temperatures of 400 deg. Cent. or below after four hours' exposure, and that (2) (*a*) the rate of oxygen penetration into "pure" copper decreased markedly below 800 deg. Cent.; (*b*) the rate of hydrogen penetration into oxygen-bearing copper decreased markedly below 700 deg. Cent.

A Large Hydro-Electric Generator.

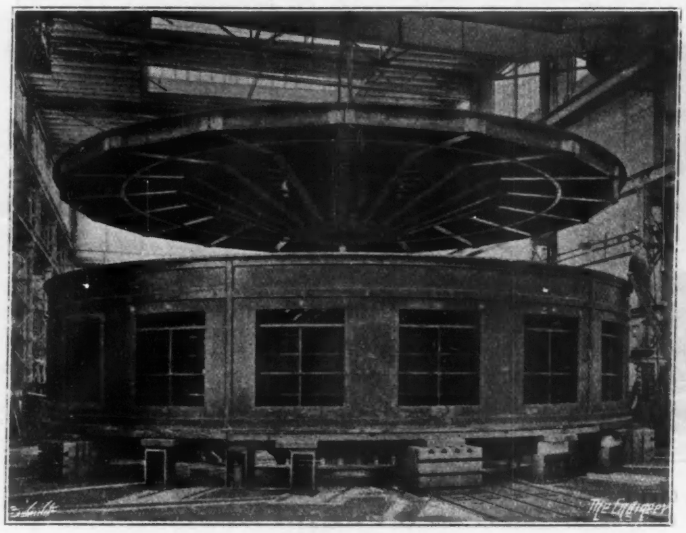

FIG. 1—STATOR WITH COVER RAISED

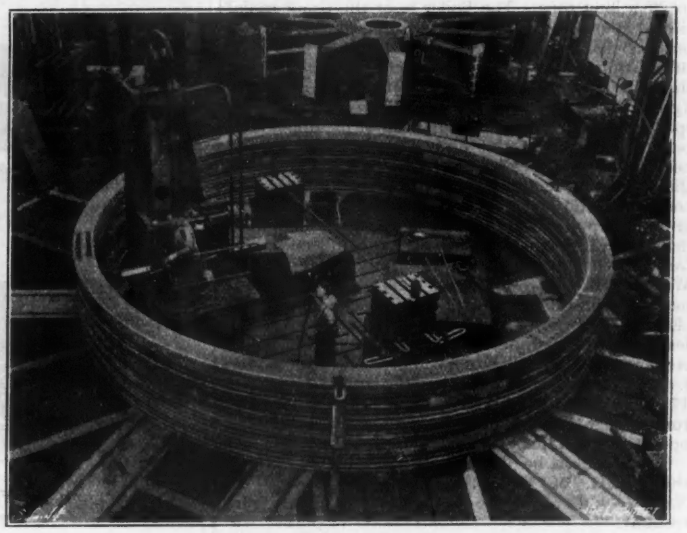

FIG. 2—ROTOR RINGS

SITUATED on the St. Louis Lake, about 25 miles west of Montreal, the Beauharnois hydro-electric power station of the Beauharnois Light, Heat and Power Company will have an ultimate capacity of 2 million horse-power. The station was described in THE ENGINEER of February 13th and 20th, 1931, and in October 30th of the same year. Constructional work was begun about 3½ years ago, with a view to providing an initial installation of fourteen main 50,000 horse-power units and two 7800 horse-power house sets, all of which will utilise the head amounting to 82ft. between the lakes St. Francis and St. Louis, connected by a channel 15·5 miles long. Ultimately, the complete equipment of the station will consist of forty-two 50,000 horse-power machines. Orders placed at present cover six 43,882 kVA, 25 cycle sets; four 46,625 kVA, 60-cycle sets, and the two 7800 horse-power units, which are also to generate at 60 cycles. All these machines are to be in service by October, 1937. One of the 43,882 kVA, 25-cycle generators, shown in Figs. 1 and 6, and on page 622, has been built by the Oerlikon Company, whilst the 53,000 horse-power Francis turbine for driving it is to be supplied by the Dominion Engineering Works, Ltd., of Lachine, Quebec. The following are the main particulars of the generator :—

Normal continuous output	43,882 kVA
Maximum continuous output	48,300 kVA
Power factor	0·85
Frequency	25 cycles
Pressure at terminals	13,200 volts
Test pressure according to the A.I.E.E.	30,000 volts
Normal speed	75 r.p.m.
Runaway speed	150 r.p.m.
Fly-wheel effect	49,200 tons × ft.^{2}
Temperature rise at normal load	99 deg. Fah.

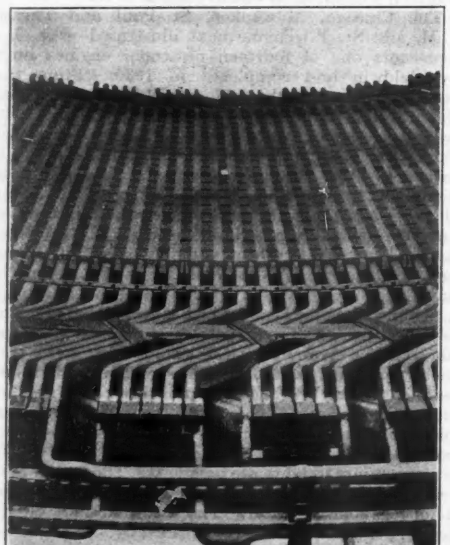

FIG. 3—PORTION OF STATOR WINDING

As the illustrations, Figs. 1 and 6, and those on page 622 indicate a fabricated construction has been adopted, the casing, which is 40ft. in diameter and 8·2ft. high, being made entirely of electrically welded steel plates. The stator, which, for reasons of transport, is composed of six parts, will be mounted on eighteen foundation plates evenly distributed around the circumference and grouted into the foundations, after the stator bore has been accurately centred relatively to the shaft. To facilitate this work, radial and vertical bolts are provided to permit of fine adjustments of the stator in all directions. Openings with suitable covers in the casing serve as outlets for the cooling air.

The laminated core plates are threaded on steel bolts welded to the casing webs, and also serve for pressing the plates together. Open slots accommodate the winding, Fig. 3, in two tiers with three conductors per slot, and arranged in several parallel circuits. Each conductor is subdivided into layers by insulating strips, and is twisted through 180 deg. in the middle of the stator. Mica tape serves for insulating the slot conductors. Special connecting lugs devised by the Oerlikon Company serve to connect the coils in a simple manner and to facilitate inspection. On either side, the ends of the coils are supported by a ring, which makes the winding capable of withstanding short-circuit stresses. Pipes and nozzles on the upper and lower sides of the winding serve to spray water on to the latter in the event of fire. As Fig. 4 shows, each phase is divided into similar circuits according to the split conductor arrangement, each being led at the beginning and at the end through a bar-type current transformer.

The current transformers S at the terminal end are connected to the relays of the differential protective gear for the outer circuit. Those at the neutral point end N are for the inner circuit, two generators working with one transformer. In the case of the inner circuit, the protective relays are set so that the differential current can rise to 10 per cent. of the normal current and to 25 per cent. in the case of the outer circuit.

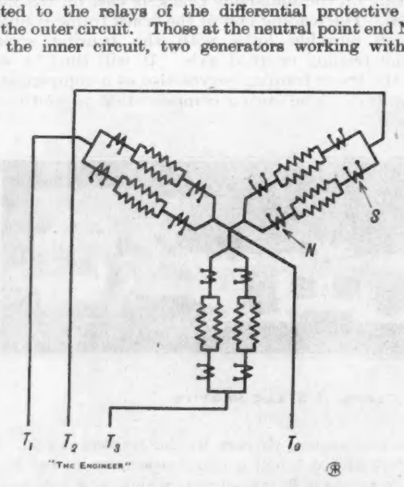

FIG. 4—ARRANGEMENT OF STATOR WINDINGS

Twelve thermo-couples are embedded in the stator windings at different points for the measurement of temperature. Leads from these couples, together with the secondary leads of the current transformers, are connected to a common terminal plate in the stator casing, and from this plate a multi-core cable runs to the control room. When completed the stator windings were subjected, in the manner shown in Fig. 5, to a test pressure of 30,000 volts for a period of one minute in the Oerlikon Company's works with satisfactory results. It was necessary, in order that the rotor, which is 33ft. 9in. in diameter, might be fully completed in the works without further adjustment on site, to subdivide the rim and spider into a fair number of parts. The pole cores are composed of stampings 1 mm. thick, riveted together and secured by keys and bolts to the rotor rings, shown in Fig. 2.

The poles are divided into ten groups, each containing four poles. Double coils composed of strip copper suitably insulated and subjected to a hydraulic pressure greater than that arising from centrifugal force, are mounted on the cores. The cast steel rotor rings, shown in Fig. 2, had to be divided into three parts in order to facilitate transport. In all there are six rings placed one above the other and separated by spaces for the passage of cooling air. Together with the poles, the weight of the rotor rings is 220 tons, which is carried by the ten arms of the rotor spider shown on page 622. The spider serves only for transmitting the torque and for carrying the weight, and does not have to deal with the centrifugal force of the poles and rings. The arms are bolted to a single-piece cast-steel hub, having a conical bore with a maximum diameter of 3ft. In view of the vertical load of 700 tons, the arrangement of the thrust bearing below the rotor is distinctly advantageous, for the reason that it permits of a considerable reduction of the supporting girder span. By means of a crane it is possible to raise the whole rotor without the shaft and without having to dismantle the thrust bearing when overhauling the machine, or when carrying out repairs. On the other hand, the thrust bearing can be removed without having to dismantle any part of the rotor, as all the bearing parts except the supporting ring are made in several pieces.

To enable the load to be taken off the thrust bearing blocks when the bearing is being dismantled, twenty-eight jacks operated with oil at a pressure of 2100 lb. per square inch are provided under the rotor rings, so that the whole of the rotating part of the generator, weighing 348 tons, can be raised. The oil under pressure is supplied by a double-acting hand pump. The jacks are also made to serve as brakes, the top of each jack being made in the form of a brake block with a brake lining. When used as brakes the jacks are worked with compressed air at a pressure of 210 lb. per square inch, the heat developed at the brakes being received, for the most part, by the lowest rotor ring.

A truck is provided for removing the parts of the thrust block laterally between the supporting girders. The ten segmental rubbing blocks of the thrust bearing are lined with white metal and carry the collars of the shaft, which is made in two pieces and has a diameter of 6ft. 10½in. Two stacks of copper tubes arranged in sections about the rubbing blocks of the thrust bearings serve for water cooling the oil supplied to the bearing. Below this bearing is the lower guide bearing in the supporting frame. The bearing brush has a bore of 3ft., and copper tubes for the cooling water are embedded in the white metal lining.

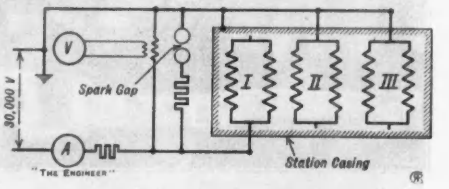

FIG. 5—CONNECTIONS FOR PRESSURE TEST

A separate exciter capable of supplying a maximum excitation current of 1080 ampères at 250 volts supplies current to the field winding through the two-part slip rings mounted on the shaft between the lower guide bearing and the shaft flange. From the slip rings the conductors for supplying the pole windings are led through the hollow shaft, which weighs 31 tons and is 23ft. 7in. long. The flange on the turbine side of the machine for coupling the generator to the turbine shaft is 4ft. 11in. in diameter.

Like the stator itself, the cover which carries the upper guide bearing is divided into a number of parts to facilitate transport. Warm air from all the sets will be discharged directly into the turbine room, and in order that this may not interfere with the proper supervision of the generators, all the instruments associated with the mechanical parts of the turbine and alternators are to be placed, together with the starting and regulating gear, at a level in the power station at which no inconvenience will be experienced. Instruments for supervising the mechanical operation of the generator will be entirely associated with the bearings. The thrust bearing and the two guide bearings each have separate lubricating and cooling systems. The instruments for supervising the latter will consist of distance thermometers, and water flow indicators, all mounted in a single case. Pipes will be provided for connecting up each bearing with an oil filter in order that the oil may be treated whilst the generator is at work. For erecting and dismantling the machines the power station is being equipped with two 160-ton cranes. The heaviest parts of the machine described are the complete upper generator cover, which weighs 28 tons; the complete stator, 174 tons; the rotor, without its shaft, 265 tons, and the lower bearings, with supporting girders and generator shaft, 95 tons. In order to handle any of these parts with one crane or with both, suitable equipment is being supplied.

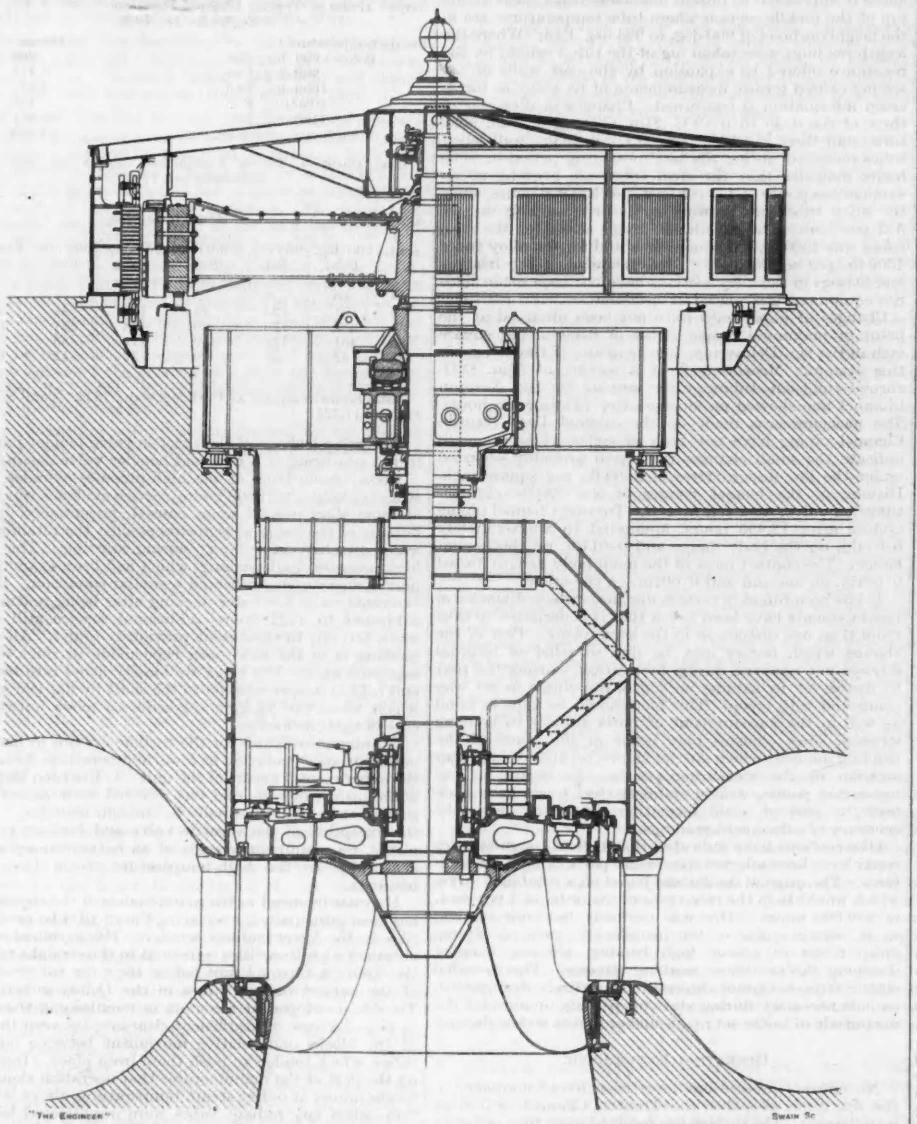

FIG. 6—VERTICAL SECTION AND ELEVATION OF HYDRO-ELECTRIC GENERATING SET

High-Temperature Steam Experience at Detroit.*

By P. W. THOMPSON, Chief Engineer of Power Plants, the Detroit Edison Company; and by R. M. VAN DUZER, Jun., Engineer, Production Department, the Detroit Edison Company.

Experience gained from equipment using steam as high as 1100 deg. Fah. in one of the power plants of the Detroit Edison Company since the fore part of 1929, leads the authors to believe that the design of steam generating plants using temperatures in the neighbourhood of 1000 deg. Fah. is entirely feasible provided users are prepared to specify the high-priced materials that experience so far dictates. A small oil-fired superheater, delivering 1100 deg. Fah. steam to a piping system has been in operation at the Trenton Channel plant since March, 1929. The information obtained in the operation of this equipment served as a basis of design for the separately fired superheater, piping and 10,000-kW turbine generator which was placed in operation with 1000 deg. Fah. steam the latter part of 1931 at Delray Power-house No. 3.

The principal trouble with the two installations has been encountered at Trenton Channel and has been caused by the leakage at flanged pipe joints. The use of better bolting material and changes in flange design have materially improved conditions. Replacement of a cracked desuperheater casting was necessary in the Trenton Channel set-up, and a new turbine throttle valve of improved design has been purchased to correct recurring leakage at the bonnet flange at Delray. With these exceptions no troubles of a serious nature have been experienced.

Examinations of the austenitic 18 per cent. chrome, 8 per cent nickel alloy which was used in the construction of the Trenton Channel superheater and piping system show that this material has deteriorated in service, due, probably, to precipitation of chromium carbides along the grain boundaries. There is, however, no evidence thus far of intercrystalline corrosion and no such serious reduction in physical properties as would lead to rejection of this material for steam service in the 1000 deg. to 1100 deg. Fah. range. Tests of other steels belonging to the low alloy class have disclosed no marked change in their properties. Since the time these two experiments were undertaken there has become available much more information concerning the behaviour of alloy steels and, this, together with advances in the art of manufacture, has made the selection of stable alloys for this class of equipment a simple matter for the designer.

Operation with high-temperature steam has presented no problems of an unusual nature. The equipment, particularly the turbine, has been given close attention because of its experimental nature. The turbine at the present time, however, is receiving only the same care as other equipment in the Delray Power-house.

This paper is primarily concerned with a discussion of the reasons for the selection of the materials that were used, results of metallurgical examination, operating features, and troubles that have been experienced and remedies applied.

Description of Equipment.

The Trenton Channel equipment consists of an oil-fired superheater supplied with 400 lb., 700 deg. Fah. steam from the station header. Approximately 65ft. of 5½in. O.D. tubing conducts the high-temperature steam to a desuperheater where the temperature is reduced before passing to one of the house service turbines. The superheater, supplied by the Babcock and Wilcox Company, is of the radiant type, containing 153 square feet of refractory covered heating surface, and is capable of adding 400 deg. of superheat to 6000 lb. of steam per hour from an initial temperature of 700 deg. Fah. The tubes which comprise the rear and side walls of the unit are covered with refractory blocks cemented to welded-on lugs on the tubes to prevent direct exposure to the radiant heat.

The Delray installation consists of an oil-fired superheater, interconnecting high-temperature piping, a 10,000-kW British Thomson-Houston turbine generator, condensing equipment, and auxiliary pumps and heaters, together with the piping necessary to connect the turbine flow circuit into the existing plant systems. The equipment occupies a space provided for a future boiler and is compactly arranged.

The superheater contains 3957 square feet of surface arranged in three sections; a top convection section, a middle semi-convection-radiant portion, and a lower radiant section which encloses the combustion chamber on the two sides and bottom. The tubes in the lower section were provided with the same type of refractory covering as used in the Trenton Channel superheater. The unit was designed to superheat 90,000 lb. of steam per hour from 700 deg. to 1100 deg. Fah., at a pressure of 455 lb. per square inch, although the ordinary operating pressure does not exceed 400 lb.

The turbine is a two-cylinder, single-shaft, 3600 r.p.m., straight impulse type unit containing nine stages in the high-pressure cylinder and eleven stages in the low-pressure portion. It was designed for steam at 365 lb. per square inch gauge, 1000 deg. Fah., exhausting to 1in. Hg. absolute. Steam is extracted at the ninth, fourteenth, and seventeenth stages for feed water heating. Except for the double casing construction, and the external supply of saturated steam which is supplied to the high-pressure shaft packing to cool the shaft and bearing, the general design of the turbine differs little from impulse turbines manufactured in this country. The generator, rated at 10,000 kW at 0·8 power factor and 4800 volts and equipped with two direct-connected exciters and a closed ventilation system, is of standard design. The condensing equipment and auxiliaries are identical with those used for the 4000-kW D.C. auxiliary turbine generators in the power-house.

Material Selections.

At the time the Trenton Channel equipment was being designed in 1927 the austenitic 18 per cent. chrome, 8 per cent. nickel alloy was being offered as the ideal material for equipment operating at elevated temperatures. Various investigators in this country and abroad had established its high physical properties and resistance to creep at temperatures in the range from 1000 deg. to 1100 deg. Fah. The principal objections to its use were the high cost and difficulties of fabricating in either the cast or wrought form.

Several different classes of so-called low-alloy steels were installed in both installations in an attempt to learn as much as possible regarding the behaviour of various alloys under the action of the high-temperature steam and at the same time find materials other than the expensive austenitic group. Aside from the saving in material cost involved in using these cheaper alloys, they are more readily fabricated into sound castings and tubing. This was illustrated by the delay and expense involved in the drawing and fabrication of the Delray superheater tubes and the pouring of the outlet fittings. It was impossible for the maker to draw and bend tubes long enough for the lower section of the superheater from the KA2B material. This section was finally completed by flash welding shorter tubes together. It was also necessary to recast the outlet fittings before sound ones were obtained.

A few tubes of medium and high-carbon calorised steel were installed in the Trenton Channel superheater to determine the degree of protection secured with aluminium coating. After the first installation of this material, 0·35 C steel tubes coated with aluminium were installed in the middle section of the Delray superheater, together with a like number of tubes coated with 18–8 and 12–14 per cent. Cr stainless steel applied with a Schoop metal spray gun.

The selection of materials for the turbine was left entirely in the hands of the turbine builder. They, working with the Brown-Firth laboratories, selected as the result of time yield tests a nickel-chromium-molybdenum alloy for the turbine throttle valve, the high-pressure shaft packing case, the inner and outer high-pressure cylinders, and the forged rotor. The time yield test on this steel at 1000 deg. Fah. showed less than a 0·5 per cent. extension during the first twenty-four hours at a stress of 5600 lb. per square inch, and no further extension during the next twenty-four hours. A maximum design stress of 6000 lb. per square inch accordingly was used in the turbine design. The original interstage diaphragms were cast from the same material, but, due to the imperfect castings obtained, these were replaced with built-up diaphragms made from a 0·40 per cent. carbon steel before operation with 1000 deg. Fah. steam. The turbine nozzle partitions and wheel blading, with the exception of the first stage buckets, were made from a 0·25 per cent C, 14 per cent. Cr, stainless steel. Hecla ATV1 containing 0·47 per cent. C, 11·8 per cent. Cr, and 36·3 per cent. Ni was used for the first-stage blading. All of the shaft packing was made from forged modified monel. The interstage packing was later changed to a stainless steel at the time the original diaphragms were replaced. Nothing unusual in the way of materials was used in the low-pressure element.

With the exception of several parts, the careful attention that was given to the selection of the materials described has so far resulted in trouble-free operation.

Metallurgical Examinations.

Results of both physical and microscopic examinations made on various materials from the two installations have shown evidence of slight changes. In no case, however, have these changes, loss in strength, or tendency toward embrittlement, progressed to such an extent that any consideration has been given to replacement of parts. It is entirely possible that the changes which have been observed will progress at a much slower rate than has occurred during the initial period of operation.

The surface of the calorised and sprayed Delray tubes is apparently in good condition except in several spots where a coarse granular appearance indicates a brittle condition. The tubes now have become coated with a $\frac{1}{16}$in. layer of slag which protects the coating from attack. The development now being made to produce a more ductile aluminium coating and its application to low alloys possessing good creep properties offers possibilities for the adoption of this class of material for high-temperature equipment.

Pipe Joint Experience.

Troubles encountered with bolted pipe joints have been many and varied. In the authors' opinion, it is doubtful whether with present materials bolted joints can be designed to give the same trouble-free operation at temperatures of 1000 deg. to 1100 deg. Fah. that has been experienced with present designs at 700 deg. to 750 deg. Fah. From experience gained, however, with the original joints at Trenton Channel, it has been possible to construct two joints that have now been in service for over 16,000 hours at steam temperatures above 1000 deg. Fah. without attention. Full strength welded joints appear to be the answer to the high-temperature jointing problem, although there is much to be learned regarding the behaviour of weld metal under stress at high temperature and the weldability of desirable high-temperature alloys.

---

* Abstracted from a paper presented at the annual meeting of the A.S.M.E., December 4th–8th, 1933.

It was rather fortunate, in one respect, that the original joints at Trenton Channel were not made heavier than the 600-lb. A.S.A. flange standard, as troubles were soon encountered which led to improvements in design. Some of the difficulties probably would not have been anticipated in the turbine installation at Delray had these joints been made more substantial. This original design led to the use of various joints which fall roughly into five classes.

Two types of stress, aside from stress due to internal pressure and bending moment imposed by change in position of a line, appear to cause most of the difficulty in high-temperature bolted joints. These are thermal stress caused by the temperature differential between the inside and outside of the joint and differences in coefficient of expansion of the joint materials, and creep stress caused by the plastic condition. In order to eliminate the thermal stresses, so-called temperature compensated joints were tried. These consisted of joints using 18–8 bolts and having spacers between the flange and nut of a material similar to Invar. The bolt and spacer lengths were so selected that any tendency to pick up or lose load was compensated for by the difference in coefficient of expansion. These joints failed, due to the rather high stresses selected and failure to consider the plastic phase at the operating temperature.

The second class of joints used were similar to the original joints with materially increased flange and bolt dimensions. Two 5in. joints in the Trenton Channel line, made up with the bolt stress limited to 10,000 lb. per square inch, have been in service over 16,000 hours. These are Van Stone type with serrated facing, KA2* flanges, steel No. 1 bolting material and $\frac{1}{32}$in. plain monel gaskets. The 900 lb. flanges in one joint were increased to 3⅜in., while the 1500 lb. flanges in the second joints were made 4⅝in. in thickness. All of the bolted joints in the Delray line, with the exception of the joints on either side of the superheater outlet valve, were made to either the 900 lb. or the 1500 lb. A.S.A. standard. Leaks which occurred in two 8in., 1500 lb. joints after 6795 hours of service were due to plastic deformation of the gasket faces rather than to dishing of the flanges or creep of the bolts.

Full strength mechanically reinforced welded joints are in service in both installations. The mechanical reinforcement, consisting of collars over three Trenton Channel joints and backing up flanges on the Delray joints, was added to prevent pulling apart should the 18–8 weld metal ever disintegrate due to inter-granular corrosion at the fusion zone. Additional time is needed to determine definitely whether such precaution is or is not necessary in 18–8 welds. It would appear from examination of the fusion zone of welding on the 18–8 tube removed from the Trenton Channel superheater that the region affected by welding does not undergo any more rapid change than the parent metal; at least when under no stress. This particular welding was used to fasten lugs to hold the tube protecting tiles. These joints have given no trouble.

Another class of joint in service, embracing the Sargol and Sarlun, is seal welded. The original Trenton Channel joints were provided with Sarlun welding lips, two of which were welded after trouble was experienced maintaining a tight-gasketed joint. During the 17,236 hours of service it has been necessary twice to repair cracks which developed in each joint as a result of bolt elongation. The modified Sargol type joints, used in the interconnecting and outlet piping of the Delray superheater, where the steam temperature varies from 850 deg. to 1000 deg. Fah., have given no trouble.

The high stresses encountered in the Trenton Channel joints and a desire to obtain satisfactory joints for the 600 lb. flanges of the valve at the superheater outlet led to the design of the hairpin type spring joint. The first of these joints installed at Trenton Channel consisted of springs, of hairpin shape, placed between the flange and one nut on each bolt. The springs were designed to maintain a unit gasket pressure of ten times the S.S.P. during the warming and cooling of the joint by compensating for the unequal expansion between flanges and bolts. The bolts were stressed to approximately 10,000 lb. per square inch and the outer end of the spring was stressed to about 17,000 lb. per square inch. The joint was remade after 1532 hours' service and has since remained tight for nearly 15,000 hours. The temperature at the highly stressed outer portion of the spring does not exceed 600 deg. Fah. with 1100 deg. Fah. steam in the line. The two Delray joints, which were designed with a maximum spring stress of 60,000 lb. per square inch, leak when being placed in service, due to water accumulation. They tighten up, however, when this water is evaporated. This design is not recommended because of the spring weight and cost. Its use was desirable in our case to prevent overstressing the valve flanges which were ordered to the 600 lb. standard before sufficient experience was obtained at Trenton Channel with this standard.

CREEP.

Troubles due to growth or creep of parts, with the exception of the difficulties encountered with the 600 lb. standard pipe joints, have been confined almost wholly to the turbine throttle valve. Excessive growth of the lower ends of the calorised superheater tubes at Trenton Channel caused their removal before failure occurred. Creep of other parts has been measured, but in no case where changes have been observed is the creep occurring at an alarming rate.

The throttle valve trouble has been caused by dishing of the bonnet joint flanges, with the result that it has been impossible to maintain a tight joint. The body itself has also exhibited changes amounting to creep rates as high as 3·5 per cent. per 100,000 hours based on measurements made during the last 6083 hours of operation. This growth caused slight binding of the main disc on one occasion.

Measurements of parts of the turbine, other than initial readings, have not been obtained except in the case of the valve chest, where a special measuring device was provided by the makers to determine the overall change in length. The changes measured have been insignificant. The last reading obtained at this location showed a slight decrease which would indicate warping. It is probable that excessive changes have not occurred in the turbine. The running characteristics have not changed and leaks have not been experienced at any of the bolted joints on the high-pressure cylinder.

The periodic measurements that have been made of the tubes in the Delray superheater are of rather doubtful value. Two types of readings are being taken from stainless steel measuring points; diameters with micrometers and length measurements with a special 20in. micrometer trammel. The close grouping of the tubes has made it impossible to obtain diameters other than at the top of the middle section where tube temperatures are in the neighbourhood of 900 deg. to 925 deg. Fah. Where the length readings were taken sag of the tubes caused by the resistance offered to expansion by the cast walls of the setting caused erratic measurements of no value as far as creep information is concerned. Changes in diameter of three of the 0·30 to 0·40 C, 2½in. O.D., $\frac{7}{16}$in. wall, steel tubes and three KA2B*, 2¼in. O.D., 0·203in. wall, alloy tubes observed during the last measuring period of 5005 hours indicates that the steel tubes are growing at an average creep rate of 4·4 per cent. per 100,000 hours, while the alloy tubes are growing at a corresponding rate of 5·3 per cent. The calculated design stress for the steel tubes was 2000 lb. per square inch and for the alloy tubes 4300 lb. per square inch. Measurements of the headers and fittings in the alloy sections have not been made since the equipment was placed in operation.

Changes of importance have not been observed at the point of maximum design stress of 6400 lb. per square inch in the 8in. Delray pipe line or in any of the fittings in this system. Measurement of a section of 5½in. O.D. chrome-tungsten tubing after service in the Trenton Channel line showed no change after 7465 service hours. The measurements made on the original 18–8 Trenton Channel piping have not been of sufficient accuracy to indicate the small changes that have probably occurred under the low design stress of 3200 lb. per square inch. Dishing of the bonnet flanges of the 600 lb. chrome-tungsten valve, removed from the Trenton Channel piping system after 12,995 hours, amounted to approximately 0·014in. on the body flange and 0·011in. on the bonnet flange. The contact faces of the main body flanges dished 0·004in. on one end and 0·007in. on the other.

It has been found in certain instances where diametrical measurements have been taken that it is desirable to take more than one dimension in the same plane. Part of the change which occurs may be due to relief of internal stresses not removed during fabrication, causing the part to distort or to assume an out-of-roundness in no way connected with creep. This fact should be kept in mind as well in the measurement of parts subject to bending stresses, since changes may occur in the plane of the bending moment which are not shown because of improper location of the measuring points. In regard to the measuring points, welded stainless steel beads have been used to prevent scale formation detracting from the accuracy of subsequent readings.

Observations have indicated that higher design stresses could have been selected for certain parts of both installations. The original design was based on a combined stress which would keep the creep rate of the order of 1 per cent. in 100,000 hours. This was probably too conservative, as in certain parts of the installation, such as piping, creep tends to relieve high bending stresses, thereby dropping the combined working stresses. The so-called elastic stresses cannot, however, be entirely disregarded, as it is necessary during start-up periods to consider the magnitude of forces set up at anchor points and at flanges.

OPERATING EXPERIENCE.

No unusual precautions have been found necessary in the operation of either the Trenton Channel or Delray installations. The turbine has received more than ordinary attention due primarily to the experimental nature of the unit rather than from any hazard connected with the use of 1000 deg. Fah. steam. Major troubles have not occurred with either the turbine or the superheater. Experience with the Trenton Channel superheater and piping system has had to do more with pipe joint troubles already mentioned in some detail. The following remarks regarding operation, therefore, are confined to the Delray apparatus.

Operating a turbine with 1000 deg. Fah. steam is little different from operating with lower superheat. The present starting cycle used in placing the installation in operation consists in starting with 700 deg. to 750 deg. Fah. steam and applying 30 per cent. load to the turbine before the temperature is increased. The same procedure, in the reverse order, is followed in taking the unit out of service. It is believed that the use of higher temperature steam would tend to complicate the starting cycle because of large temperature differences which would exist in the turbine. It is the authors' opinion that units which may in the future be built for 1000 deg. Fah. operation should be provided with either a low-temperature source of starting steam or a desuperheater in the turbine lead to prevent the occurrence of severe high thermal stresses during the starting period.

A clearance indicator mounted at the front end of the high-pressure cylinder showing the movement of the rotor relative to the casing has been used as a guide in determining a safe rate for changing load or steam temperature. The forged rotor, a smaller metal mass than the casing and in more intimate contact with the steam, is more responsive to temperature changes. Its movement is watched, therefore, to prevent going below a safe minimum axial clearance of 0·010in. to 0·014in. on the leading edge of the fifth wheel. No maximum rates of load or temperature change have been determined, but load has been applied at the rate of 1000 kW per minute from 30 per cent. to full load without producing vibration or a clearance change exceeding 0·045in. Normally load is changed at a rate of 1000 kW per 3 to 4 minutes and temperature is changed at a rate of 100 deg. per hour. This last rate is an arbitrary one and might be exceeded without difficulty. Attention should be given to this detail of running clearance in any turbine designed to operate at high temperature or under rapidly fluctuating load conditions.

During the initial period of operation the steam temperature was increased in increments of 25 deg. to 50 deg. above 900 deg. Fah., allowing the unit to operate approximately one week at each temperature until 1000 deg. Fah. was reached. During this period of operation growth of the throttle valve packing sleeve occurred, causing the stem to bind. The original semi-steel bushing was replaced with one having a nitrided surface and no evidence of growth has since been observed. Similar bushings in the five control valves were also renewed with nitrided parts as a precaution.

TABLE.—*Service History of the Trenton Channel and Delray Installations.*

Service Hours of Trenton Channel Installation, March 4th, 1929, to September 1st, 1933.

Steam temperature.	Hours.
Below 900 deg. Fah.	360
900 deg. Fah.	1,471
1000 deg. Fah.	4,420
1050 deg. Fah.	438
1100 deg. Fah.	16,311
Total hours in service	23,000

Load Duration, Delray Installation, October 1st, 1930, to September 1st, 1933.

Load, per cent.	Hours in service.					
	700 deg. Fah.	800 deg. Fah.	850 deg. Fah.	900 deg. Fah.	950 deg. Fah.	1000 deg. Fah.
20	40	6	2	3	—	3
40	191	123	28	106	41	3545
60	327	170	60	438	377	1959
80	404	139	480	211	85	582
100	62	38	19	37	12	1743

Total hours in service at 1000 deg. Fah., 7832. Total hours in service, 11,231.

Recurring leakage of the throttle valve bonnet joint led to the procuring of a new and heavier valve casting.

Upon examination of the high-pressure cylinder inter-stage packing after 3809 hours' service evidence was found of more than normal wear, caused, presumably, by the binding of the packing segments against the retaining pin which resulted in rubbing during starting. The outer high-pressure shaft packing, which had been examined on previous occasions, indicated a similar condition. Recent examination of the outer packing after being refitted and subjected to 7422 hours' additional service still shows wear, but not to the extent previously found. All of the packing is of the saw-tooth type made in rings of four segments each. The rings are loosely fitted into tee slots and held in proper relation to the shaft by flat leaf springs which allow the packing segments to move outward in case of shaft deflection.

Maintenance figures for the turbine are not in line with other turbines operating at lower temperatures because of the experimental nature of the unit. It has been inspected at frequent intervals and has received more attention in general than would normally be thought necessary. With the exception of the throttle valve and bushing replacements, no maintenance costs of an extraordinary nature chargeable to the high-temperature steam have been incurred.

Expense incurred in the maintenance of the superheater has been principally for replacing the small tube-protecting tiles in the lower radiant section. The excellent results obtained with these tiles cemented to the straight tubes in the Trenton Channel unit led to their use for protection of the curved radiant tubes in the Delray superheater. Trouble developed at the start in maintaining these tiles in place because of insufficient clearance between the ends of the blocks and relative movement between adjacent tubes, which tended to push them from place. Insistence on the part of the manufacturer that operation should not be continued at outlet steam temperatures above 900 deg. Fah. when any radiant tubes were unprotected led to a change in the method of insulating the back of the tubes. Tie bars, holding the tubes in groups of twelve, were added to reduce the relative movement of adjacent tubes, and the tile shape was altered slightly to provide greater clearance between tiles. These changes have materially improved the service continuity of the refractory lining. At the present time, should a tile drop out of place during operation, the temperature is not lowered and the tube is allowed to remain bare until the next shut down.

Water collecting in the U-shaped tubes forming the furnace bottom has complicated the starting process somewhat. The procedure is to admit no steam to the superheater until after the fire has been started and temperatures of about 300 deg. Fah. are indicated on the tube thermo-couples located at the bottom of three arbitrarily selected tubes. The power-operated relief valve at the outlet is then opened to provide a sufficient circulation of steam to carry out any remaining water. Conditions are then satisfactory for admitting steam to the turbine for starting.

The Trenton Channel installation has now been operated for a total of 23,000 hours and the Delray equipment has been operated for 11,231 hours up to September, 1933. The hours of operation at various temperatures are shown in detail in the table.

CONCLUDING COMMENT.

In summing up the experience recorded to date with the two high-temperature installations, the information that has been gained on various types of construction and the results of metallurgical examinations would indicate that the use of steam equipment at temperatures as high a 1000 deg. Fah. is entirely feasible. It is safe to say that a plant could now be built to operate on 1000 deg. Fah. steam and that reliable service could be expected. Although the authors may have appeared to stress the shortcomings and difficulties, it is not their intention to convey the idea that these are of a serious nature or in excess of the general run of troubles to be expected with any equipment of an entirely new and untried design.

It is not the purpose of this paper to present the economics of such a choice of steam conditions. In the authors' opinion it is doubtful whether such a selection could be justified if high-temperature resisting materials now available were used. Further metallurgical research may produce such materials at a much lower cost which will in the future give economic justification to the use of 1000 deg. Fah. steam.

* 90,000 lb. tensile with 40 per cent. elongation in 2in.

Railway and Road Matters.

The new general secretary of the National Union of Railwaymen, to succeed Mr. C. T. Cramp, who died suddenly on July 14th, will be the late assistant secretary, Mr. J. Marchbank.

It is announced that Mr. Arthur R. Cooper, the chief engineer to the London Passenger Transport Board and President of the Permanent Way Institute, has consented to remain in the latter office for another year.

It is stated that the Southern Railway Company's all-Pullman train, the "Southern Belle," is to be known in future as the "Brighton Belle." We would add that this particular train first ran on December 10th, 1888.

When the Railway Returns for 1932 give the percentage of steam locomotives in use out of the number available, those, in a serviceable condition, withdrawn from service and stored is excluded. Those engines numbered at the end of the year 1135, and the number in use was 89·30 per cent. of the remainder available. The engine-hours in traffic per weekday were 11·68, and the engine-miles run per weekday were 102·99 per locomotive.

In asking the sanction of the Railway Rates Tribunal to the Great Western Railway Company reducing its rates for the carriage of wood to one-fifth of the standard rate, Mr. Cole Deacon, for the company, said that this was a very heavy reduction, but it was necessary if the railway was to be able to compete with the road companies, which collected the goods direct from the farms in large lorries fully loaded. The application, which is for a period of six months, was granted.

In connection with the presentation by the Brighton Corporation to the Southern Railway company's s.s. "Brighton," of a painting by Mr. Leslie Carr, it was stated that that boat, having a speed of 25 knots, was estimated to be the fastest merchant vessel of her size afloat. As related in our Seven-Day Journal, of April 14th last, this vessel, which was placed in the Newhaven-Dieppe service on the 10th of that month, is the fifth of that name to be employed in the service of the Southern Railway and its predecessor, the London, Brighton and South Coast.

The Southern Railway Company has just placed an order with William Denny and Brothers, of Dumbarton, for a paddle steamer for the Portsmouth-Ryde service. She will be the sixth new vessel placed on the service during the last ten years, the others being the "Shanklin" in 1924, the "Merstone" and "Portsdown" in 1928, and the "Southsea" and "Whippingham" in 1930. The new boat will have a speed of 14½ knots, and will be licensed to carry about 900 passengers. She will have triple-expansion engines, and will be ready to take her place on the service next July.

A rather suggestive question was addressed to the Minister of Transport on December 11th. Sir William Davison was wishful to know when the rolling stock and motors of the Inner Circle trains of the Metropolitan Railway were last inspected. The answer was that the Minister had no power to make any such inspection, but the annual report of the railway company included a certificate to be signed by the chief mechanical engineer to the effect that the rolling stock had been maintained in good working condition. That certificate appeared in the Metropolitan Railway report for 1932.

A deputation from the Ilford and District Railway Users' Association waited upon Lord Ashfield and the London Passenger Transport Board on Thursday, December 7th, as to the construction of a tube railway to Ilford. The deputation was told that the Board recognised the seriousness of the position, and had made a careful study of the problem in collaboration with the L. and N.E.R. Company. As far as the Board could estimate, there was not the slightest possibility of the services being self-supporting. Lord Ashfield added that the Board had been asked by the Minister of Transport to report on the subject, and the report would be ready shortly.

The fatal collision of December 6th, at Altrincham, mentioned herein on the 15th, was inquired into, on behalf of the Ministry of Transport, by Colonel Trench. As we read the evidence in the *Manchester Guardian*, it would seem that after the first train had arrived in No. 2 platform, the signalman in the South box opened the points for the train to set back into a siding. Hearing, that man said, two "pops" on the whistle, he concluded, in the dense fog that prevailed, that the movement was completed and lowered the signals for the second train. The standing train had not, however, moved, and the collision resulted. Answering a question by the N.U.R. representative, the signalman said that had the platform line been track circuited, the collision could not have occurred.

The Medway Canal was authorised in 1792 in order to give direct communication by water between the Medway at Rochester and the Thames at Gravesend and so avoid the longer journey by the Nore. A short time after railway communication was established in this country the Gravesend and Rochester Railway and Canal Company was formed. It was to convert the canal into a railway. The South-Eastern Railway Company subsequently obtained a lease of the undertaking, and in 1845 Parliament confirmed that transaction and sanctioned an improved scheme. Railway communication between the two points was established on August 23rd, 1847, but it was not until July 30th, 1849, that the North Kent line at Greenwich was extended to Gravesend, and there was through rail communication between London and Rochester *viâ* Gravesend. The canal was only filled in as between Rochester and Higham and there still remained 4½ miles of canal thence to Gravesend. The Railway Returns for 1932 show that the canal carried 36,243 tons of traffic during last year, which, however, brought in only £247, to which sum had to be added £1776 for canal dock dues and £195 for rents. Against this was an expenditure of £1560. The canal is now the property of the Southern Railway Company, which is seeking Parliamentary powers to transfer that portion which lies in the borough of Gravesend to the Gravesend Corporation and to abandon the remainder of the canal.

Notes and Memoranda.

The car-miles travelled by the trams of Great Britain decreased during the year by 4·69 per cent., while the passenger journeys decreased by 6·40 per cent.

The Smithfield-street Bridge in Pittsburg was built in 1882, and was considered to be too weak for modern traffic, but it has been given a new lease of life by putting in an aluminium floor.

In a paper read before the Institution of Engineers, Australia, Mr. F. H. Harrison, works manager of the Islington repair shops of the South Australian Railways, said that the use of the acetylene blow-pipe in the repair of copper locomotive fire-boxes had resulted in a saving to the railway of £25,000 in three years.

The issue of the *Journal of Scientific Instruments* for November contains an illustrated article on soldering and brazing by A. S. Newman and Dr. R. S. Clay, which will be found most useful by workers in scientific laboratories. It describes the conditions under which soft and hard soldering can be carried out most successfully, the best fluxes to use, and the proper way to apply them and the solder. Special methods for tubes and for manganin wires are described, and handy forms of burners, clamps, and cutting tools are shown.

Investigations at the Pittsfield works of the General Electric Company have indicated that a lightning rod not only protects the structure upon which it is erected, but also a considerable area around it. A low lightning rod is particularly effective in this respect in proportion to its height. A rod 100ft. high will protect a flat area surrounding it for a distance of approximately 400ft. from the base of the rod when the storm cloud is not lower than 1000ft. A 500ft. rod will protect over a radius of approximately 650ft. and a 1000ft. rod over a radius of at least 1000ft., assuming a flat area in each case.

An apparatus for testing the soundness of welded joints is described in *A. E. G. Progress*, No. 3, 1933, as follows :—The welded seam is magnetised by two permanent magnets, magnetically linked by an iron core. If defective spots are present the field is distorted. The course of the magnetic field is explored by a probing device consisting of an amplifier and headphones. A search coil located in the head of the probing device is made to vibrate by means of a magnet energised from the supply voltage. When the device is glided slowly over the welded seam, any alteration in the loudness or tone of the sound produced shows that defects are present. The seam can be explored rapidly, and after a little experience the kind of noise produced is sufficient to diagnose the nature of the fault.

An interesting application of a mercury switch has been made at the plant of an American cement company to control the feed to 10ft. conical mills in the raw grinding plant. These mills, which operate in a closed circuit with the air separators of the plant, are controlled by inserting a depression gate in the oversize chute of the air separator. The gate is connected by a linkage to a mercury switch which operates a revolving gate in the chute from the feed bin to the main conveyor. As the feed to the mill increases or decreases the depression gate is raised or lowered according to the quantity of material flowing through the chute, the change in position thus making or breaking the contact of the mercury switch. The latter energises or de-energises the solenoid on the revolving gate, which locks or releases that gate, controlling the flow from the feed bin to the conveyor.

Reports have appeared, says *The Iron Age*, to the effect that Russia is conducting researches toward solving the problem of producing aluminium from low-grade clays. The actual facts from a reliable source are to the effect that the Russians have few deposits of good bauxite and are, consequently, reported to have been spending time and money in the extraction of aluminium from clay. This is also true of Germany. It is technically feasible to extract aluminium from clay, and, in case of war, such a process might be of distinct value if the supplies of bauxite were cut off. None of the processes, however, so far described in the literature, or the processes which have been described as being the ones investigated by the Russians, would have any possibility of competing in cost with the current commercial processes for extracting alumina from bauxite.

In a paper read before the Institution of Chemical Engineers, Messrs. Bengough and Whitby described the successful application of their selenium process for the protection of magnesium alloys against marine corrosion. Specimens were immersed for 5–15 minutes in a solution containing 10 per cent. selenious acid and 0·5 per cent. sodium chloride, at ordinary temperature, and were then subjected to four months' exposure to sea-water spray, applied thrice daily, without suffering appreciable attack. The success of the process is attributed largely to the self-healing properties of the film, which are thought to depend upon the following reactions. The magnesium surface becomes coated with a thin layer of magnesium selenide, which is decomposed by water penetrating through pores in the selenium layer. The hydrogen selenide thus formed reacts with oxygen to give selenium, which seals the pores through which the water penetrated.

In a paper by M. J. Burgess and R. V. Wheeler, just issued by the Safety in Mines Research Board, an account is given of experiments carried out to ascertain the possibility of preventing the igniton of firedamp, caused by the striking of coal cutter picks against quartzitic sandstone by discharging an inert gas, carbon dioxide, into the cut made by the machine. In these experiments the carbon dioxide, in the solid form as used commercially, was carried on the coal-cutting machine in a standard liquifier, and the gas was directed through a copper pipe into the machine cut at the end of the jib. With the machine cutting against sandstone in an explosive atmosphere, it was found that while some ignitions of firedamp occurred when carbon dioxide was discharged into the machine cut at rates below 1½ cubic feet per minute, they were much less frequent than when no carbon dioxide was used, and when carbon dioxide was used at rates above 1½ cubic feet per minute no ignitions occurred. The paper may be obtained from H.M. Stationery Office, price 6d.

Miscellanea.

A rubber factory is to be put up at Travancore.

It is proposed to establish an aerodrome near Colombo, Ceylon.

A new passenger air service between Cairo, Luxor, and Assuan has been opened.

An aerodrome is to be constructed on the outskirts of Shanghai at a cost of £200,000.

During the past year the number of telephones in Great Britain has increased by 60,000.

Some extensive deposits of kaolin in the Soanlathi district of Finland are to be developed.

More gold was produced in the first nine months of this year in Australia than in the whole of 1932.

A large factory for the manufacture of synthetic rubber is being put up at Yaroslav, Russia.

A special pavilion is to be erected at the forthcoming Levant Fair by Imperial Chemical Industries.

Three ferry boats are to be built for the Trustees of the Clyde Navigation by Barclay, Curle and Co., Ltd., of Glasgow.

The Bombay Port Trust Railway is buying its supplies of 90-lb. rails and fish-plates from the Tata Iron and Steel Company.

The U.S. War Department announces plans for the purchase of 7776 motor vehicles for the mechanisation of the Army.

A new rolling mill for heavy work, with a daily capacity of 1500 tons, has been started at the Ilyich works at Mariupol, Russia.

The L.N.E.R. has placed orders with iron manufacturing firms at Nottingham, Blaydon-on-Tyne, Middlesbrough, Thornaby-on-Tees, and Alloa for 3480 tons of cast iron permanent way chairs.

The new carbonising plant of the Tottenham and District Gas Company, at South Gate, Willoughby-lane, Tottenham, which was formally inaugurated by the Duke of York on December 12th, has cost £125,000.

The Burntisland Shipbuilding Company, Fife, has received orders for a cargo steamer of 2850 tons from Messrs. Glen and Co., Glasgow, and a 1160 tons steamer for the London and Channel Islands Steamship Company.

A new turbo-generator of 12,000 kW, manufactured at the Stalin Works at Leningrad, is undergoing tests in the Moscow power-house. When this machine is in commission, a number of large Moscow buildings, including the Grand Opera, will be electrically heated.

The Government of Madras is understood to have issued orders sanctioning the construction of transmission lines for taking power from the Pykara Hydro-electric Works from Erode to Trichinopoly. The estimated cost of constructing these lines will exceed Rs. 20,00,000.

A message from Baghdad, published in *Indian Engineering*, states that the Anglo-Egyptian combine, Nuttall, Mowlem, Brand and Abboud (Near East), Ltd., has submitted the lowest revised tender (just under £1,000,000) for the Habbaniya Barrage on the Euphrates. The tenders are now being examined. The object of the scheme is to protect the lands of the Lower Euphrates from floods in the spring, and give the cultivators of Iraq more water for their crops in the late summer.

Plans are under consideration for the erection of a sulphuric acid plant in Palestine, the raw material to come from the sulphur deposits of Ghaza. It is understood, says the *Chemical Trade Journal*, that a decision to erect the plant is likely to be taken, since Palestine Potash, Ltd., are to embark upon the production of potassium sulphate from their crude potash salts. Superphosphate is also likely to be made in Palestine in the near future, utilising the domestic phosphate rock resources.

H.M. Consul at Kovno reports that he has been given an assurance by the Lithuanian Government that, in anticipation of the conclusion of a treaty between the United Kingdom and Lithuania, national treatment in respect of taxation will be accorded to British commercial travellers. The effect of this concession will be to exempt British commercial travellers from payment of the licence tax of 1050 lits., but it will not affect their liability to the professional tax of 50 lits. per month. In order to secure this exemption, commercial travellers must produce to the Lithuanian authorities a certificate of identity issued by an approved British Chamber of Commerce, and drawn up in accordance with the form prescribed by the "International Convention for the Simplification of Customs Formalities," which was signed at Geneva in 1923.

There died recently at his home in London an engineer whose active interest in his profession extended over nearly seventy-five years. Mr. H. C. Powell was born in 1842 and went to King's College, London, in 1858, while as recently as the end of 1932 he contributed some notes on aeronautics to a technical journal. He was associated with several important steps in engineering progress. Being on the staff of Mr. J. F. Spencer, when the North-Eastern Marine Engineering Company was formed, he became chief draughtsman in the works at Sunderland. Later he was engineer to the Antofagasta Nitrate Company and Railway in Chile. Then for ten years he managed the works of his cousin, M. Thomas Powell, at Rouen, where, besides other notable productions, the "Simplex" gas engine with electrical ignition was made in 1888. At that time he was also instrumental in putting a water-tube boiler in a tug on the Seine. This interest led to his acquaintance with M. Niclausse, with whom he negotiated the taking over of the manufacture in England of the Niclausse boiler by Messrs. Willans and Robinson at Queensferry. During the last twenty years Mr. Powell paid several visits to South America for engineering firms, and kept in touch with current developments in all branches of engineering, sending occasional communications to the Institute of Marine Engineers, of which, as well as of the Institution of Mechanical Engineers, he was a member for many years.

Development of the Parsons Steam Turbine.

The steam turbine is one of the landmarks in engineering industry. Coming at a time when the electrical age was beginning, it both made large scale electricity supply possible and was made by it. The first turbo-generator made under Parsons' patent of 1884 developed about 7·5 kW; single turbo-generators over 100,000 kW capacity are now running. The present estimated value of Parsons turbines alone is £152,000,000, the figures for marine and land turbines being £92,000,000 and £60,000,000 respectively. Nothing to equal that rapid extension of value and dimensions has ever happened before.

Before the death of Sir Charles Parsons we had taken preliminary steps for the publication of a series of articles on the development of the Parsons turbine to celebrate its jubilee. The preparation of that series has been delayed by one cause and another, and can now not benefit by his personal supervision, but if it lacks anything of the vivid touch which he might have given, it still remains a most fascinating history. We need scarcely say that the publication of the series, which will begin on January 5th, 1934, will occupy many weeks, but the history is one in which every engineer takes a deep interest and pride, and we have no doubt that our articles will be widely read and appreciated.

THE PRINCIPLE OF SIMILITUDE.

THE paper by Dr. Griffiths and Mr. Awbery, presented before the Institution of Mechanical Engineers on Friday of last week, was concerned with the transfer of heat between metal pipes and a stream of air. The temperature and other conditions of the experimental work on which the paper was based were such as to make the results chiefly applicable to the design of refrigerators and low-temperature air heaters. That being so, the particular appeal of the paper covers a somewhat narrow and specialised field. In one respect, however, it touches upon a subject of wide general interest. It provides an excellent example of the complexity of much modern research work, and of the advantages and limitations of the principle of similitude as a means of simplifying the presentation of the results. The object of the investigation was to measure the heat transfer and to determine in what manner it was affected by the diameter of the pipe, the temperature of its surface, the velocity of the air impinging upon it, and by other factors. At least ten variable factors are involved in the problem if a single pipe alone is considered, while several others are added if the pipe is one of a bank. To investigate the effect of each variable separately and to present the results in a readily comprehensible and applicable form would have been an arduous if not an impossible task. Resort was therefore made, as it is now commonly made in physical research under similar conditions, to the principle of similitude, that great generalisation of which Newton had some perception and to which the late Lord Rayleigh gave formalised expression. In its elements there is nothing either mysterious or abstruse about that principle. It centres on the requirement that any mathematical equation which we may devise to express an objective relationship between two or more quantities must, if it is to be rational, involve the fundamental units of length, mass, and time equally on both sides. In other words, the "dimensions" of both sides of the equation must be the same. If the dimensions on one side are, for example, $M L^2/T^2$—that is to say, those of energy—then those on the other side must also add up to $M L^2/T^2$. If they do not, the equation is wrong, and cannot express any relationship which could possibly exist in the physical world. The principle of similitude is particularly concerned with the case in which the dimensions of both sides add up to zero. If out of a multiplicity of factors affecting or likely to affect an observed result, we can choose or form two groups, each of which has zero dimensions, then, according to the principle of similitude, it is rational to search for a relationship between the two groups. Alternatively, if two groups have different dimensions, it is a waste of time to endeavour to find a relationship between them.

If the number of variables affecting the observed result is known to be restricted to not more than three the complete form of the relationship between the observed result and the variables can be discovered by a direct application of the method of dimensions. For example, the factors affecting, or possibly affecting, the periodic time of a simple pendulum oscillating through a small arc are the length of the cord, the mass of the bob, and the acceleration due to gravity. These three factors have to be combined in such a way as to make their dimensions add up to that of time. It is easy to prove that they can so add up only if the mass of the bob is without effect on the periodic time, and only if that time is determined by the square root of the length of the pendulum and by the reciprocal of the square root of the acceleration, g. The method of dimensions leads in this case directly to the precise relationship sought, namely, $T=k\sqrt{l/g}$. where k is a pure number. If, however, there are more than three variables affecting the observed result, the method of dimensions presents us with the insoluble problem of finding the values of four or more unknowns by means of three equations. In the case of Dr. Griffiths and Mr. Awbery's problem, the observed result was the quantity of heat energy transfer between the pipe and the air per unit length of the pipe per unit of time. The dimensions of this observed figure were, therefore, those of energy divided by length divided by time, or $M L/T^3$. The variable factors affecting, or believed to affect, the observed result, had, therefore, to be combined in such a way as to make their dimensions add up to unity with respect to mass and length and minus three with respect to time. A more general method of procedure—that actually adopted by Dr. Griffiths and Mr. Awbery—is to form from the variables a combination having the same dimensions as the observed result, and to divide the observed result by this combination so as to produce a group of zero dimensions. Then, if any relationship exists at all between the observed result and the variables supposed to affect it, it will lie between this dimensionless group and some other dimensionless grouping of the variables. This method of discovering a physical relationship is extraordinarily attractive, both from the practical point of view and because of its fundamental significance. It has, however, several limitations. It is not always possible to compile a list of the variable factors affecting the given result with complete assurance that it omits none which should be included, and includes none which should be omitted. For example, in the case of the simple pendulum already mentioned, a variable, the amplitude of swing, is omitted, although *a priori* we ought to expect it to affect the periodic time. The justification for that omission is derived not from the principle of similitude, but from precedent observation of the behaviour of simple pendulums and an analysis of that behaviour by the processes of general dynamics. Again, if the number of variables in the list is at all considerable, it is nearly always possible to form from them several groups having zero dimensions. Which of these groups should be selected for correlation with the dimensionless group containing the observed result? The principle of similitude gives us no guidance. It does not even tell us that there is bound to be a relationship between each and every pair of dimensionless groups that can be formed. All that it says is that if a real relationship exists it will be found between one such pair of groups. The selection has, therefore, to be made either by a process of trial or by guidance provided by previously acquired experimental or analytical knowledge. A third and very important element limiting the application of the principle of similitude arises if the problem under investigation involves thermal considerations. What dimensions are to be assigned to temperature, or to any factor, such as thermal conductivity, involving temperature in its composition? The usual procedure is to assign to temperature zero dimensions with respect to length, mass, and time, and to give it a special dimension, θ, of its own. On this basis the dimensions of temperature are $M^0 L^0 T^0 \theta^1$ and of thermal conductivity, $M^1 L^1 T^{-3} \theta^{-1}$, and to the dimensions of all quantities which do not involve temperature we may, if we please, add the symbol θ^0. This practice ensures that a proper account is taken of temperature and prevents the possibility of a relationship being sought between two groups of factors which are of the same dimensions with respect to length, mass, and time, but differ with respect to their temperature dimension. On the other hand, the practice has a restrictive effect, for if dimensions in length, mass, and time can be assigned to temperature, additional non-dimensional groups can be formed from the variables entering into a thermal problem. These groups are ignored if temperature is given a special dimension θ, yet it may quite well happen that among them is the group that we are seeking. The selection of some other group in these circumstances can at best yield only an approximate relationship, and may result in the experimental investigation being directed along lines that will miss the point.

The suggestion that temperature has dimensions with respect to length, mass, and time, and that there is no necessity to assign to it a special dimension of its own, is not novel. It arises naturally from the kinetic theory of gases. According to that theory absolute temperature is proportional to, and is a measure of, the kinetic energy possessed by unit mass of the gas. Since energy has the dimensions $M L^2/T^2$, energy per unit of mass has the dimensions L^2/T^2. Hence, it would seem that the dimensions of temperature are two with respect to length and minus two with respect to time, or, in other words, that they are identical with the dimensions of a velocity squared. A consistent list of the dimensions of all other thermal quantities can be drawn up if these dimensions are assigned to temperature, and each entry in that list, being expressed in terms solely of length, mass, and time, can be homogeneously combined with any non-thermal variable. For example, the dimensions of thermal conductivity now become $M^1 L^{-1} T^{-1}$. The dimensions of heat, it may be remarked, remain unaltered at those of energy, those of specific heat become zero, while entropy per unit mass and R the gas constant in the equation $p v=R T$ become pure numbers. From the practical or experimental point of view, the assignment of length and time dimensions to temperature has a bearing which may be of much importance in the interpretation and application of the results. If the variables include temperature and the velocity of a stream of fluid, as in Dr. Griffiths and Mr. Awbery's work, then $\sqrt{T}/V$ is non-dimensional, and therefore in order that the principles of dynamical similarity may be fulfilled, any change in the velocity V of the stream ought to be accompanied by a proportional change in the square root of the temperature. It is possible that the omission of this observance may have accounted for certain discrepancies in Dr. Griffiths and Mr. Awbery's results, and for their difficulty in fitting them to a rational law based on the principle of similitude.

The Cunard Liner.

No news in recent years has given quite the same satisfaction, both in engineering and industrial circles, as the statement made by Mr. Neville Chamberlain, the Chancellor of the Exchequer, in the House of Commons last week on the subject of financial facilities for the building of the Cunard liner "No. 534," now on the stocks at John Brown's Clydebank yard. Mr. Chamberlain said that he was glad to inform the House that the difficult and complicated negotiations, which had been conducted with great goodwill on all sides, had reached a stage at which the Government felt justified in assuming that an effective merger of the North Atlantic fleets of the Cunard and White Star lines would become an accomplished fact at an early date. In that event it was the intention of the Government shortly to lay before the House proposals for furnishing the necessary financial facilities for the completion of "No. 534." In reply to a question as to whether the proposals would contain any reference to the possible construction of a second ship, Mr. Chamberlain said that it would be better to await the Government's proposals. According to official statements which have since been made by the Cunard and the White Star companies, the two companies are in touch with one another, both directly and through their solicitors, and are busily engaged with the drafting of the many documents which the proposal entails. Both national and technical reasons for the construction of the Cunard liners were given in our leading article of October 7th, 1932, entitled "Build the Cunarders." We have little to add to that statement.

There are many preliminary matters to be settled before work can actually begin at Clydebank, but it is confidently expected that operations will be restarted early in the New Year, and that the resumption of work upon the ship will be progressive. It is satisfactory to learn that the hull is in the best of conditions, both as regards its alignment and with regard to its protection from rusting. As is well known, the building berth is that which the "Aquitania" occupied at Clydebank, strengthened and extended where necessary. Its structure has proved so sound that no perceptible change in position of the hull has taken place. The technical staff of John Brown and Co., Ltd., under the leadership of Sir Thomas Bell, is to be congratulated on the success which has attended its constant care of the hull and its supports, and the protection of the framing and plating from corrosion. When work on the liner was stopped close upon two years ago, much had already been done by the Clyde Navigation Trustees towards preparing the bed of the river Clyde for the launch. That work is now so well advanced that it will be easily completed before the ship is ready for launching, sometime next year.

Heat Transfer Between Pipes and Air.

THE INSTITUTION OF MECHANICAL ENGINEERS.

ON Friday evening of last week Dr. Ezer Griffiths and Mr. J. H. Awbery, both of the National Physical Laboratory, presented before the Institution of Mechanical Engineers a paper entitled "Heat Transfer between Metal Pipes and a Stream of Air." This paper, an abridgment of which will be found elsewhere in this issue, was originally prepared as a report to the Engineering Committee of the Food Investigation Board, of which Committee Sir J. Alfred Ewing is Chairman.

Following Dr. Griffiths' presentation of the paper in summary, Sir Alfred Ewing was called upon by the President, Mr. A. E. L. Chorlton, to open the discussion. Sir Alfred said that the Food Investigation Board was one of the most active sections of the Department of Scientific and Industrial Research, and, like other bodies set up by that Department, consisted of a judicious combination of practical men professors, and scientists. Nearly all the research work for the Board had been conducted at the National Physical Laboratory, and very largely under the control of Dr. Griffiths, to whose skill and care as an investigator the Board was deeply indebted. The main purpose of the investigations described in the paper was to obtain data which would assist refrigeration engineers to design banks of pipes for cooling air, but it was later realised that the results obtained had a wider general interest to mechanical engineers, and hence the report was offered as a paper to the Institution. The striking new fact brought out by the research was the immense effect on the heat transfer produced by turbulence in the air. He pictured the air striking the first row of a bank of transverse tubes and flowing round the tubes of that row in a streamline manner until some way round the rear half of the circumference where a certain amount of turbulence would develop. The second row of tubes therefore received the air in a turbulent condition, and passed it on in a still more turbulent condition to the third row, a limiting state of turbulence being subsequently reached. That condition, he said, served to explain why it had been found that the heat transfer increased from row to row towards a limiting value. There could be no doubt whatever that air in turbulent flow was in a better condition to pick up heat or to part with it than air in streamline flow. The difference was as great as that between the solution of sugar in a cup of tea when the tea was stirred and when it was not stirred.

Dr. C. H. Lander said that the increased heat transference at the second and third rows of a bank of pipes was a very interesting and unexpected fact. At the Imperial College of Science Dr. Fishenden and Mr. Saunders were at present conducting an investigation on the transfer of heat between a heated surface and a fluid in motion past it. The experimental method employed was based on the fact that in the region adjacent to the surface there was a substantially stationary layer of the fluid across which the temperature dropped at a uniform rate. If a beam of light were directed to pass axially through the stationary layer it would be deflected—see Fig. 1—and it could be shown theoretically that the deflection x was proportional to the heat transference at the section of the heated surface under examination. When a tube exposed transversely to a current of fluid was examined in that manner, the image of the deflected rays passing through the stationary layer produced a closed figure, the radial distance between which and the boundary image of the tube was proportional at any point to the heat transference occurring at that point. In nearly every instance the figure cast by the deflected rays was not an exact circle, but slightly heart-shaped, indicating that the heat transference was not uniform all round the tube wall, but was affected by some difference in or adjacent to the stationary layer. When a group of three tubes was exposed to a transverse stream of air the images were distorted in the manner shown on the screen—see Fig. 2. It would be noted that the heat transference over the lower portion of the upper tube had been greatly increased by the presence of the two lower tubes. By integrating round the circumference of the tube, the total amount of heat transferred could be calculated. The slide did not altogether support the authors' finding as to the increased efficiency of the second row of tubes in a bank. It must, however, be remembered that it showed only one tube in the second row, and that, judging from the effect on one another of the two tubes in the first row, the addition of a second and third tube in the second row would considerably increase the heat transfer of the central tube.

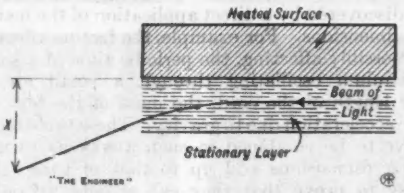

FIG. 1

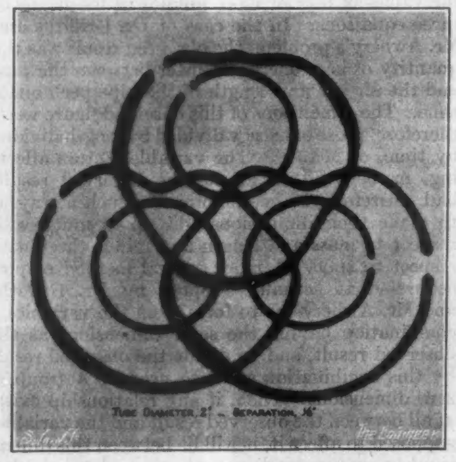

FIG. 2

Dr. Margaret Fishenden, dealing with the effect produced by artificially created turbulence, commented upon the fact that such turbulence raised the heat transfer of the first layer in a bank by about 100 per cent., and that of the second by about 50 per cent., thereby bringing the heat transfers of the two layers into practical equality. The level to which the heat transfers of the first and second rows was thus raised was found to be greater than that of the heat transfer from the third, fourth, and fifth layers without artificial turbulence. Dr. Fishenden thought this fact was curious, for it seemed to suggest that without artificial turbulence, the induced turbulence at the third and later layers did not really represent the limiting value. Was it possible, she asked, that the effect of artificial turbulence was confined to the first and second layers, and that thereafter the heat transfer fell towards the limiting value corresponding to the turbulence induced at the later layers when no artificial means of creating or increasing it was employed ?

Mr. F. C. Johansen criticised the authors for assigning dimensions to specific heat. Specific heat, he said, represented the ratio of two quantities of heat just as specific gravity represented the ratio of two weights, and was, therefore, a pure number. The quantity which the authors used as specific heat should preferably be called volumetric heat capacity. Dealing with the authors' method of presenting their results, he said that their selection of the dimensionless quantity $H/k\,\theta$ was not wholly satisfactory as it did not include a velocity term. It was, in his opinion, essential to include velocity in the variable if the coefficient was to be a true constant. Various dimensionless variables could easily be devised which would include velocity. For example, both $h/c\,V\,\theta$ and $h\,\nu/k\,V\,\theta$ were dimensionless. The fact that the heat transfer depended upon the Reynolds number emphasised the close connection which existed between heat transference and aerodynamical resistance. In the case of a long cylinder exposed to a transverse flow of air, the aerodynamical resistance was found to be fairly constant for Reynolds numbers lying between 4 and 5, and over that range he would expect that there would be a corresponding fairly uniform heat transference law. Above 5 and below 4, however, the aerodynamic resistance changed in such a way as to suggest that there would be great changes in the heat transference law. He, therefore, suggested that the empirical law deduced by the authors from their single tube experiments would be found to be applicable only to conditions duplicating the Reynolds numbers of the authors' experiments. In plotting their curves the authors had in all cases continued the curve without inflexion until it met the vertical axis at a point representing the heat transfer for zero velocity of the air. Some experiments which he had conducted on a hot wire anemometer for use in calibrating a pitot tube to work at very low velocities revealed the fact that at very low velocities the heat transfer from the wire was actually less than when the velocity was zero—that was to say, the static convection was actually greater than that produced by a very low velocity. The heat transfer curve had, therefore, a minimum at some velocity greater than zero, and from that minimum rose up to intersect the vertical axis at the point corresponding to the heat transfer at zero velocity. Some similar inflexion in the curve would probably be found to apply in the authors' case. Dealing with the authors' experiments on the heat transfer to cold pipes, he commented upon their observation that the heat transfer was greater when the pipes dripped water than when they were dry. He could not quite understand the action which was taking place when water was dripping from the pipes, but if the observation were correct, it seemed reasonable to suggest that practical advantage would accrue in a cold store if the air at the inlet to the cooler were kept very moist.

Professor A. L. Mellanby thought that the authors might do something to facilitate the task of any one who had to design from the data given in the paper a practical air heater or air cooler. He commented also upon the comparisons which the authors made between their results and those of others. In view of the considerable amount of agreement which they apparently had found, he desired to ask them whether they thought that the work described in the paper had really been worth while, or whether it amounted largely to the repetition of the work of other investigators.

Dr. J. N. Long asked whether the snow which formed on the cold pipes maintained a circular outline. Aerodynamically there was a region of positive pressure extending round a section of about 78 deg. of angle at the front of a circular pipe exposed transversely to a wind stream, the remainder of the surface being under a negative pressure. He would have expected that in the authors' cold pipe experiments the snow which formed would reflect that fact and would pile up on the positive pressure side, giving the coated pipe other than a circular section. He agreed with Dr. Mellanby concerning the omission from the paper of certain data that would be required by practical designers. For example, no information was given concerning the number of tubes in a bank which would be required to give a stated amount of cooling. He also commented upon the absence of information regarding the effect of pitching the first two rows at wider intervals than the others, a practice which, he said, he thought would in time become common.

Mr. W. F. Cope commented upon the authors' statement that they had been unable to find any reference to previous work on the transfer of heat between a pipe and air flowing axially along its outside surface. A great deal of work had been done on the transfer of heat between a pipe and a fluid flowing along its interior. Comparing the authors' results with experiments on the heat transmission in locomotive boiler tubes, he found that the heat transfers obtained by the authors were about 20 per cent. greater. In the case of heat transfer in condenser tubes, however, the figures were in marked agreement with the authors' results. That fact was surprising in view of the great difference in the conditions.

Dr. A. P. Thurston said that it was well known that the cooling effect of a stream of air impinging on a hot wire was proportional to the velocity of the air and its density. It was evident from the authors' results that the same law applied in the case of a pipe laid across a current of air. In aerodynamics it had been found that if two similar cylinders were exposed to an air current, and if the gap between them were reduced progressively, a point was reached at which the combined air resistance of the two pipes suddenly became less than that of one pipe alone. That fact led him to ask whether the authors had made any experiments in which the spacing between the tubes in the rows had been varied. He also suggested that it might be worth while investigating the effect of rider planes attached to the outside of the pipes. Such rider planes had been shown to have a marked effect on the air resistance of cylinders, and it was possible that they might similarly affect heat transfer.

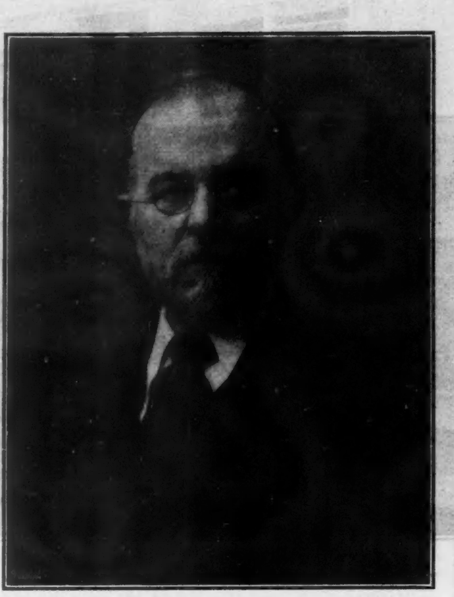
Mr. J. H. Awbery, replying to the discussion, expressed the hope that many more results might be forthcoming from the method of studying local conditions of heat flow described by Dr. Lander. The limiting value of the turbulent effect had puzzled them very much. The fact that the heat transfer for the third, fourth, and fifth layers was substantially the same, seemed to suggest that at these tubes the turbulence reached the limit of its effect. Yet it was undoubtedly true that artificial turbulence could increase the heat transfer for the first and second rows above the limiting value for the third and later rows when artificial turbulence was not used. It would seem that the limit of turbulence which the bank of tubes could produce was less than that which could be produced artificially. It might possibly be as Dr. Fishenden had suggested, that with artificial turbulence the heat transfer would in the later pipes revert to the limiting value which it would have had if artificial turbulence had not been used. He was far from being sure whether specific heat was a dimensional or a non-dimensional quantity, just as he was not sure whether specific gravity was a pure number or so many grammes per cubic centimetre. It was quite possible that some form of selected variable other than that which they had chosen might be more advantageous to users of the data collected during the research. There was no reason why the change should not be made. Replying to Mr. Johansen, he said that his suggestion seemed to be that if water dripping from the pipes gave a better heat transfer, a still better result would be achieved by running a cooling bank under such conditions that that water turned to ice, thereby giving the bank the benefit of both the latent heats. In such a condition the bank would not be operating under steady conditions, for if ice were forming on the pipes their diameter would be growing. Dealing with Dr. Mellanby's remarks, he said that the comparison of their results with those of others showed not unnecessary duplication, but differences amounting in some cases to as much as 50 per cent. The snow on the cold pipes did not deposit uniformly all round. The shape was peculiar, but it was too difficult to measure or draw accurately. They had, therefore, assumed that the snow-covered pipe was externally circular and of a diameter corresponding to its measured periphery. Actually, the shape was much as it would be if it corresponded to the distribution of pressure and suction round the pipe. They had not as yet investigated the effect of varying the pitch uniformly throughout the bank. Still less had they studied the effect of unequal pitching of the pipes. He thought Dr. Thurston's suggested use of rider planes on the pipes was an interesting one, and would like to investigate their effect.

Obituary.

DR. JAMES TAYLOR MILTON.

MARINE engineers and naval architects throughout the world will learn with regret of the death of Dr. J. T. Milton, a late Chief Engineer Surveyor of Lloyd's Register of Shipping, which took place at his home at Emsworth, Hampshire, on Wednesday, December 13th.

Dr. Milton, who was eighty-three years of age, was born at Portsmouth, served his apprenticeship in Portsmouth Dockyard, and studied at Greenwich College, where he was one of the outstanding students of his year. In May, 1875, he joined Lloyd's Register of Shipping as an engineer surveyor, and at once took a share of the outdoor surveying work of the Society in the London district, and of the work of the Engineering Department. When he joined the Society it had no rules for engines and boilers. He it was who framed the first rules, and during his long period of service made successive revisions of them, formulating new rules as fresh problems arose. His tenure of office covered an interesting period of rapid advance and change in marine engineering practice. Some outstanding developments which he saw and advanced were the use of Siemens-Martin basic steel for boilers; the introduction of corrugated furnaces; and the coming, first, of the triple-expansion, and then of the quadruple-expansion engine with increased boiler pressures. Another important advance was the introduction of the Parsons steam turbine, first with the direct drive, and then with reduction gearing. Shortly afterwards there followed the Diesel and other oil marine engines, and the use of oil fuel for boiler firing. In all these developments Dr. Milton kept fully abreast of the advances made and formulated appropriate Lloyd's rules. From May, 1875, to June, 1921, when he retired from the office of Chief Engineer Surveyor, which he held with honour from 1890, Dr. Milton only spent four years away from Lloyd's Register of Shipping. In 1886 he left the Society to become manager of the marine engine works of R. and W. Hawthorn, Leslie and Co., Ltd., but he returned in 1890 to take up the position of Chief Engineer Surveyor.



DR. J. T. MILTON

He was a member of the Institution of Civil Engineers, and a recipient of the Telford Medal. In June, 1921, the University of Durham conferred upon him the honorary degree of Doctor of Science. Among other offices he was a Vice-president of the Institution of Naval Architects, a Past-president of the Institute of Marine Engineers, and a member of the North-East Coast Institution of Engineers and Shipbuilders, the Institute of Metals, the Liverpool Engineering Society, and the Ice and Cold Storage Association, of which Society he was at one time a President. He served on several Government Committees, dealing with petroleum and oil fuel problems, and was a member of the Committee appointed by the Cunard Steamship Company to advise on the most desirable type of machinery for the "Lusitania" and "Mauretania."

Dr. Milton presented several important papers to the various technical institutions, among which may perhaps be mentioned that of April, 1911, on "Diesel Engines for Sea-going Vessels," read before the Institution of Naval Architects, in which he gave a valuable account of Continental progress with the Diesel engine. He was a personal friend of the late Dr. Rudolf Diesel, and was largely instrumental in putting forward his claims in this country. In April, 1914, Dr. Milton further reviewed the oil engine position in a paper read before the Institution of Naval Architects on the "Present Position of Diesel Engines for Marine Purposes." Other papers included his Lloyd's report of May, 1912, on the "Spontaneous Combustion of Coal," and several papers before the Institute of Marine Engineers dealing with such important subjects as cast iron, brass, and other copper alloys used in marine engineering.

To few marine engineers has there been granted a more useful, varied, and honoured life. The end came suddenly and peacefully following the shock of the death of his illustrious brother, Engineer Rear-Admiral Milton, who died a few days before his brother James, also at Emsworth.

The late Admiral Milton was aboard the "Calliope" at the time of the Samoan hurricane, and carried out many Admiralty trials, including some of the first in which the Admiralty put the engines from full ahead to full astern without shutting off steam.

TOM CRAVEN.

WE have to record with regret the death of Mr. Tom Craven, who for half a century was an active partner in the firm of Gresham and Craven, Ltd., of Manchester, which was founded by his father. He was also for many years a director of Beyer, Peacock and Co., Ltd. He was eighty-three years of age, and although he had lived in London since his retirement, he used for a time to make regular visits to the works.

SIXTY YEARS AGO.

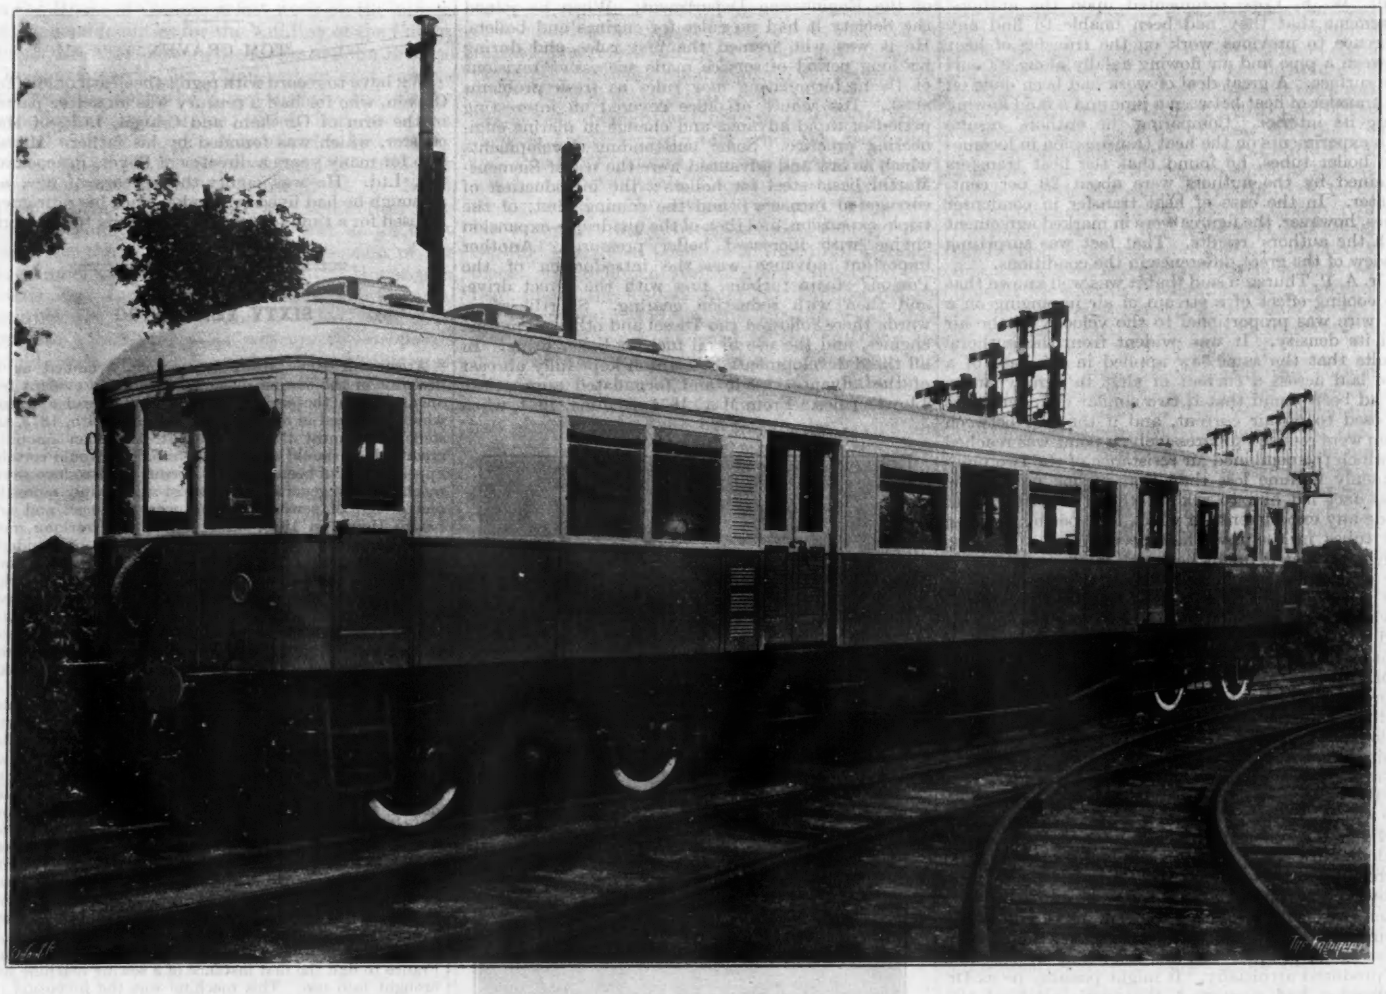
ALTHOUGH Elias Howe is commonly named as the inventor of the sewing machine, it is quite evident from an article on the early history of that useful appliance, which appeared in our issue of December 26th, 1873, that some doubt must always exist as to the exact amount of credit which should be given to him. He would certainly appear to have been the first person to introduce sewing machines into general use, but just as certainly more than one design of sewing machine was produced and tried before Howe, in 1845, finished the first working model embodying his ideas. To Thomas Saint of London a patent was granted in 1790 for a method of making boots. In Saint's specification a design of sewing machine working a chain stitch with a single thread, an awl and a needle, was briefly described. Saint's patent specification was for a long time hidden in the archives of the British Patent Office, and was only brought to light by an American sewing machine manufacturer in 1872, when seeking evidence to support the great attack on the validity of the Howe patents. Even, however, if we omit Saint's claim to priority, we have to take account of more than one other invention which preceded Howe's. Thus in 1804 Stone and Henderson—presumably two Englishmen—were granted a French patent for a machine intended to imitate hand sewing. This machine worked with an ordinary needle, which was passed backwards and forwards through the fabric by a pair of jaws which turned its point towards the fabric at each passage. In England, about the same time, several embroidering machines were invented, notably Duncan's of 1804, which with very little alteration could have been converted into chain-stitch sewing machines. In 1818 Adams and Dodge, of Monkton, Vermont, produced a sewing machine of some sort, but little is known of it. It would seem that we have to go to France to find the first instance of a sewing machine being brought into use. This machine was the invention of a poor tailor, Barthlemy Thimonnier, of St. Etienne. It was produced in 1839 and was constructed of wood. Beaunier, an engineer, saw the machine and persuaded Thimonnier to take it to Paris. A company, Ferraud, Thimonnier, Germain, Petit et Cie., was formed and established a factory in the Rue de Sèvres in 1841. Eighty wooden machines were installed and were set to work on a contract for Army clothing. Within less than a year, however, a mob of workpeople attacked the factory, destroyed the machines, and drove the inventor from Paris. In 1847 Thimonnier's machine was taken up by Magnin, of Villefranche, who patented it in his own name in England, and eventually sold his rights in it to a Manchester company. In 1848 another workshop equipped with the machines was set up in Paris, but it, too, was attacked by a mob. Concerning the respective claims of Hunt, Howe and Singer in the United States, the position is and must always remain obscure. Chronologically, Walter Hunt in 1834 came first, but it is not certain whether his was a practical machine. Howe is stated to have conceived his idea in 1839. His machine and Hunt's possessed considerable similarity, but there is every reason to believe that the duplication was unconscious. Singer came on the scene when Howe's machine was just beginning to attract attention. Singer caused Hunt to reconstruct one of his machines and sought to oppose Howe's claims. There was much litigation, which ended in Singer agreeing to pay Howe a royalty. In this country Howe was forestalled by Fisher and Gibbons, of Nottingham, who, in December, 1844, made and patented a machine for working ornamental designs on lace. This machine embodied the elements of a Howe sewing machine to such an extent that it was held to invalidate Howe's patent, parts of which were accordingly disclaimed.

IN essence, the instrument installed in the National Physical Laboratory for standardising radio wave lengths is a tuning fork of the same general form as that used by musicians as a standard of pitch, and the researches which have enabled the extraordinary degree of accuracy of modern radio communication to be reached consist of experiments on methods of mounting the fork and of securing exact balance of its two prongs; an investigation of the effects of slight changes of temperature and atmospheric pressure, and the means of avoiding them; a study of the electrical circuit used to maintain the fork in continuous vibration, and the magnetic coupling of this circuit to the form; and, finally, the means of determining to the highest accuracy the frequency of the fork. The complete standard equipment includes a chronograph specially designed by Dr. Dye for this purpose. Mere inspection of the chart of this instrument enables the frequency of the fork to be read with an accuracy of one part in ten million in terms of time, as measured by the standard clock of the Laboratory. This would represent a deviation of not more than about 8 seconds a year if the fork was running continuously for that period.

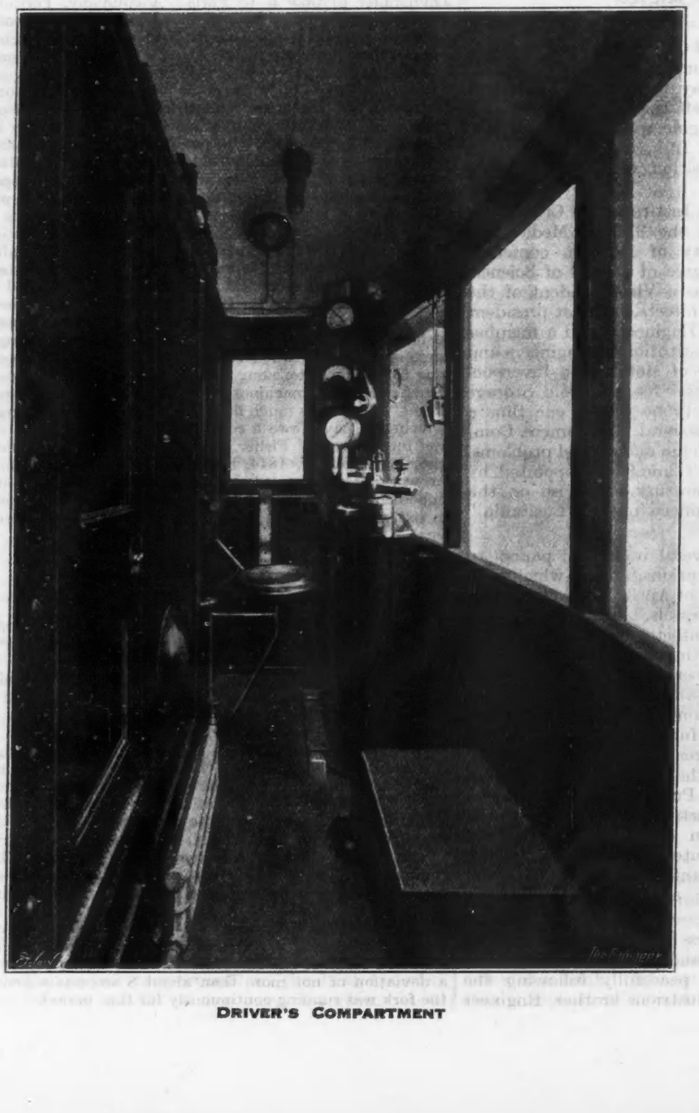
OIL-ELECTRIC RAIL COACH

THE ENGLISH ELECTRIC COMPANY, LTD., ENGINEERS

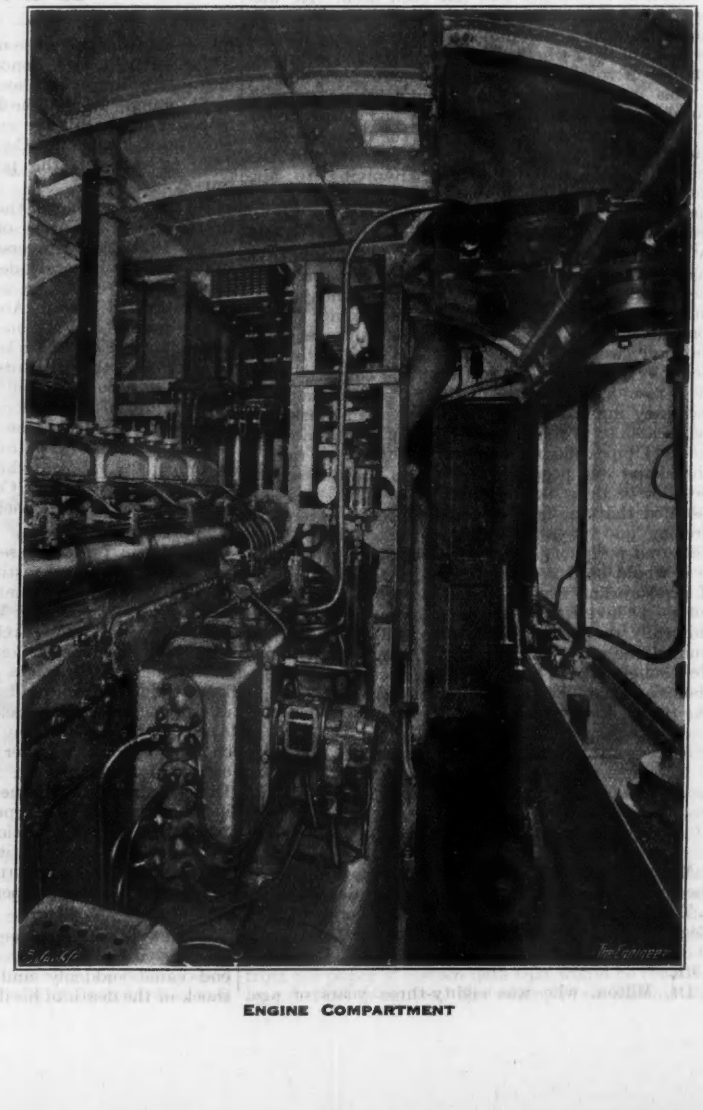
(For description see opposite page.)



200 H.P. OIL-ELECTRIC RAIL COACH



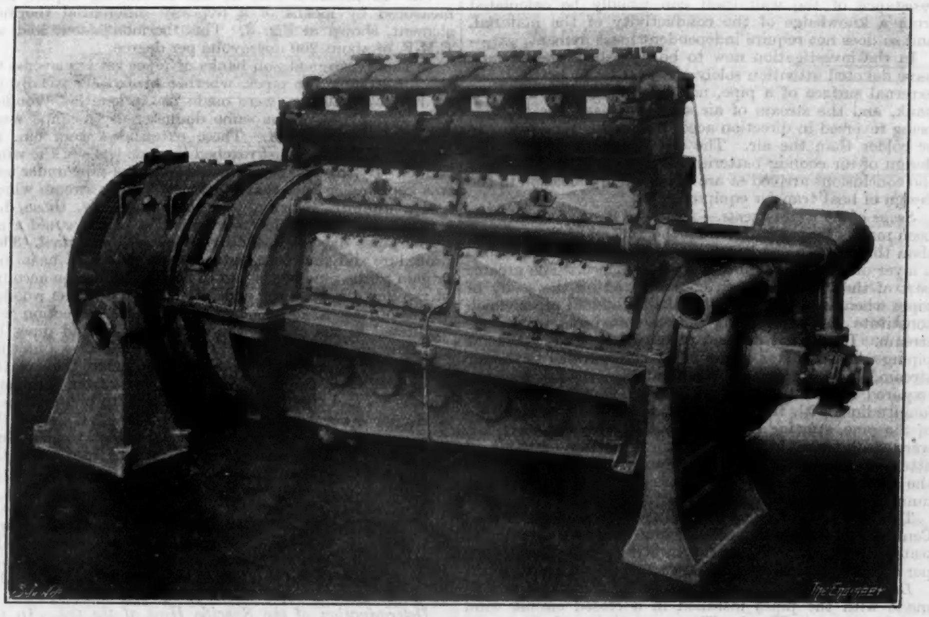
DRIVER'S COMPARTMENT



ENGINE COMPARTMENT

200 H.P. Oil-Electric Rail Coach.

ALTHOUGH the English Electric Company did pioneer work in the development of rail vehicles equipped with internal combustion engines, it has always maintained that the best system of propelling trains is governed by conditions, and that when considering the question of using motive power other than steam, each case should be examined individually in the light of all requirements. At the company's Dick, Kerr works, Preston, much experience in the construction of internal combustion engine rail vehicles has been gained. During the war many 40 horse-power petrol-electric locomotives were built. Subsequently, 100 horse-power petrol-electric rail car equipments were made for the Uruguay State Railways, a 50-ton, 100 horse-power petrol-electric breakdown locomotive for the Montreal Harbour Commissioners, electrical equipments for 200 horse-power oil-electric rail cars on the San Sebastian–Pamplona Railway, Spain, and complete 200 horse-power oil-electric coaches for the Venezuela Central Railway. In conjunction with Armstrong, Whitworth and Co., Ltd., the company also provided the electric control and motor equipments for the three oil-electric mobile power-house trains described in our issue of Nov. 25th, 1932, and for the oil-electric locomotives put into service this year on the Buenos Aires Great Southern Railway. Examples of vehicles fitted with mechanical transmission by the Company's association with the Drewry Car Company are the 100 horse-power motor coaches and the 300 horse-power locomotives which were built at the Dick, Kerr works, Preston, and supplied by the Drewry Car Company to the Bermuda Railway.



Power Unit of Oil-Electric Rail Coach

A 200 horse-power English Electric oil-electric rail car has recently been put into service on the Watford–St. Albans branch of the L.M.S. Railway. The coach body and bogies were built at the maker's Preston works, the engine at the Willans' works, Rugby, and the electrical equipment at the Phœnix Works, Bradford. Designed for branch line working, the coach is capable of hauling a standard 27-ton trailer coach and of performing incidental shunting work, such as necessary on branch lines in this country. Illustrations of the complete car, and the engine and driving compartments are given on the opposite page. The leading particulars of the vehicle are :—

Length over buffers	62ft. 10½in.
Length over body	59ft. 6in.
Width overall	8ft. 11⅜in.
Height overall	12ft. 11⅛in.
Seating capacity as at present arranged ..	53
Maximum seating capacity	61
Weight in working order, but without passengers or baggage	37½ tons
Maximum speed	60 m.p.h.

Composed of rolled steel sections riveted together, the underframe is well braced and gussetted. A swing bolster at the engine end carried by four swing links with nests of four spiral springs and rubber shock absorbers, serves to eliminate vibration. Finished in hand-polished mahogany and bubinga, with mahogany mouldings, the interior of the passengers' compartment presents a fine appearance. All-metal fittings are chromium plated. The seats are upholstered in figured moquette, and have removable cushions. Passengers enter the coach through a centre entrance controlled by sliding doors. A total of fifty-three seated passengers can at present be carried, but by a variation of the existing seating plan the number can be increased to sixty-one. Above the waist line at the trailing end of the coach the partition between the driver's cab and the passengers' compartment is composed of glass, so that during the day a view is obtained through the coach end, which is covered by blinds at night. A luggage compartment divides the passenger compartment from the engine-room, the bulkhead on the passenger side being lined with sound-deadening material. The engine-room is composed of steel throughout, and a removable roof allows the power unit to be lifted out for a complete overhaul. Where there is insufficient headroom to allow of this, however, the end of the coach body can be removed to permit the power unit to be drawn through the end of the coach on rollers.

Driving controls are provided at each end of the vehicle, and the equipment is designed to permit of multiple unit working. The plate frame type bogie under the engine compartment carries two axle-hung driving motors. The trailing bogie is built up of steel sections, and like that under the engine compartment it has S.K.F. roller bearing axle-boxes. A vacuum brake acts on all the wheels, while a screw-down hand brake operating through the power brake rigging, acts on the wheels of the driving bogie.

The power unit shown below consists of a vertical four-stroke English Electric mechanical injection cold starting six-cylinder oil engine, coupled to a 135-kW generator built and rated in accordance with traction practice. The engine, with 6in. by 8in. cylinders, develops 200 horse-power at 1500 r.p.m., and will give a maximum output of 220 horse power for 15 min. Running speeds of 1200 and 900 r.p.m. are available when the full output is not required. From the master controller the engine speed is controlled by a patented system, involving the use of solenoid operated valves to admit the lubricating oil under pressure to control cylinders, which alter the governor control spring settings and the timing, and arranged so that in the event of the oil pressure failing the engine is shut down. A centrifugal pump driven from the crank shaft circulates water through the engine jackets and radiator, which incorporates an oil cooler. Trunnions are arranged to give a three-point suspension for the engine and generator, and stresses in the crank case or shaft due to whipping or strain in the coach underframe are avoided. The arrangement not only makes a heavy bed plate unnecessary, but also avoids the need for special rigidity in the coach underframe. With a view to reducing the noise and vibration transmitted along the coach to a minimum, the power unit bearers and their fixing bolts are insulated with rubber from the underframe. A separately mounted chain-driven exciter has been provided to reduce the overall length of the set. The control gear, comprising the reverser, motor contactors, battery cut-out, &c., is assembled in a frame mounted over the main generator, and the making of connections between this apparatus and the external cables is facilitated by the provision of terminal bars, so that the control gear frame can be quickly disconnected and dismantled for overhaul or repairs. An electrically operated exhauster is mounted in the engine compartment.

Much consideration was given to the design of a heating system suitable for warming the rail coach and any trailer it may be called upon to haul. While electric heating from the main or auxiliary generator only calls for simple equipment, heat is only obtainable while the generator is running. This entails running the engine light in order to pre-heat the coach before putting it into service, and as the engine is shut down during periods of coasting, and while standing in stations, it is difficult to maintain an adequate temperature in the passenger compartments. Another disadvantage of the electric system is, of course, that it is impossible to supply heat to ordinary trailer coaches, equipped for steam heating. For the same reasons heating from the engine exhaust or circulating water is also unsatisfactory, and a low-pressure steam heating system, using a boiler fired with the same oil as employed for the engine, has therefore been adopted. Steam circulates through radiators fitted under the seats of the passenger compartment, and the condensate returns to the boiler through a feed tank. Apart from the occasional replacement of water rendered necessary to compensate for losses, the system is fully automatic. If for any reason the boiler flame is extinguished or the boiler water level falls to the limiting point, the oil supply is interrupted. The feed pump is automatically controlled by the water level. At each end of the coach there are standard hose couplings, so that steam can be supplied to any standard passenger coach used as a trailer.

Less than one hour's tuition is said to have been necessary to make men who are quite unfamiliar with this type of vehicle competent drivers. While the car is running the engine-room calls for no attention, and the control is very simple. The vehicle is designed for one-man operation, the master controller having a dead man's button. After a push-button switch, which sets up the circuit for motoring the generator from the battery, has been operated, movement of the master controller handle raises the engine speed from the idling value up to 1500 r.p.m. in three steps, and then weakens the traction motor field. If the controller handle is moved back towards the idling position the weak motor field position is retained until the idling position is reached, so that economy of engine power is combined with maximum electrical output.

By bringing the master controller handle to the engine "Shut down" position, advantage can be taken of coasting periods, station stops, &c., to secure economy by putting the engine out of service. Excessive overload currents and overloading of the engine are avoided by the arrangement of the generator windings and the method of controlling the excitation. At the same time, however, the full power output of the generator is automatically maintained over a very wide range of train speed. There is no need for the driver to watch instruments while driving. A set of signals, consisting of two red and two white lights in the driving cab of the rail coach and trailer, serve to indicate whether there is adequate lubricating oil pressure and correct water circulation. In the event of failure of either of these services, the red light glows and gives the driver immediate warning. The red lights also glow when the engine is shut down, so that if the driver is stationed at the trailing end of the car or is driving from a trailer coach he has no difficulty in ascertaining whether the engine is at work.

By the courtesy and co-operation of the L.M.S. Railway, the rail car is being tested under service conditions on various portions of the company's system. In the first instance runs were made on the Warwick–Daventry–Northampton branch, on which the car ran as a single unit or with trailing loads of cattle trucks, horse-boxes, &c., as required. Although oil-electric vehicles are available twenty-three hours per day, the present running arrangements are made to suit the company's requirements and to work in with existing time-tables, and on the named branch the car has been in service fifteen hours per day and five days per week. During the five weeks ending November 11th, the vehicle ran 5880 miles at an average fuel consumption of 6·26 miles per gallon or 5·22 miles per gallon, including the heating boiler fuel, which works out at 0·5 gallon per hour for coach service. The figures include mileage and running time expended in shunting at wayside stations, shed movements, and other incidental running. The table below gives the results obtained during the period mentioned in greater detail.

Date, week ending.	Solo miles.	With trailer, miles.	Total miles.	Approx. total ton/miles.	Fuel oil engine, gallons.	Fuel oil boiler, gallons.	Total gallons.	Engine fuel miles per gallon.	All fuel miles per gallon.	Eng. fuel, lb./ton-miles.
14/10/33	1,014	146	1,160	48,270	193·0	44·0	237·0	6·00	4·90	0·0356
21/10/33	995	168	1,163	48,664	198·4	38·0	236·4	5·85	4·92	0·0360
28/10/33	1,094	129	1,223	45,020	183·8	34·25	218·05	6·65	5·60	0·0360
4/11/33	997	173	1,170	42,200	182·8	31	213·8	6·4	5·46	0·0380
11/11/33	1,021	142	1,163	42,540	181·9	39·5	221·4	6·4	5·30	0·0375

As we have said, at the present time the coach coupled to a standard trailer equipped with a driving end is working on the Watford–St. Albans service. Steps taken to avoid the transference of noise and vibration from the engine compartment to the passengers' compartments, as the result of this service running, have, we are informed, proved entirely successful. Smooth acceleration and good riding qualities have been secured, and passengers travel in comfort.

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

MULTIPLE MARINE OIL ENGINES.

Sir,—I read with interest your report in last issue of Mr. Ricardo's paper in which he advocates small engines for marine propulsion. This proposal to use many small engines instead of one large one raises arguments for and against, and a few points might be of interest. Engines of similar design, over any range of sizes, if run at their maximum speeds, consistent with safety from damage by inertia stress or centrifugal forces, will not have the same r.p.m., but will naturally have the same piston speed as one another. It follows from this that the work per minute done in a cylinder of each is in proportion to its cross-sectional area—that is, the horse-power increases in proportion to (cylinder diameter)^2. But the engine weight increases in proportion to (cylinder diameter)^3. Therefore,

$$\frac{\text{Engine weight}}{\text{Horse-power}} = \frac{(\text{dia.})^3}{(\text{dia.})^2} = \text{dia.}$$

That is, Weight *per horse-power* is increased in direct proportion to cylinder diameter in engines of similar design.

From this we can reasonably assume that a power installation having engines of 4ft. stroke will have its total engine weight twelve times that of an installation having the same total horse-power by engines of 4in. stroke. If these engines are direct-coupled to dynamos, the same argument might be applied to engine and dynamo combined.

So far the small engine has the best case.

The question next would be how much everything else increases in weight as engine size is reduced, also how the complication is added to.

Finally, large Diesel engines operating with air blast injection are suited to, and have time in their slow revolution to, consume the crudest fuel, while the small engine requires a distillate fuel and has hardly time to consume that properly in its quick revolution.

The real solution might possibly be found in using engines of 12in. or 15in. diameter cylinder bores, of full Diesel type with air blast, which are not exacting in fuel quality, and of which ten six-cylinder engines should give a total of 6000 horse-power, with a sensible engine-room.

December 13th. JAMES A. NEILSON.

BRITISH STANDARDS INSTITUTION.

All British Standard Specifications can be obtained from the Publications Department of the Institution at 28, Victoria-street, London, S.W.1. The price of each specification is 2s. 2d. post free, unless otherwise stated.

LECLANCHE-TYPE PRIMARY CELLS.

No. 397—1933. The first edition of the B.S. specification for Leclanché-type primary cells was published in 1930, and was immediately adopted by all the large purchasers of cells. Seldom has a specification been so widely quoted by purchasers, and worked to by manufacturers in so short a time. The experience thereby gained has enabled extensive data to be collected and a revision to be undertaken. The second edition differs from the first in two main respects. An alternative electrolyte to ammonium chloride is now provided, this being a mixture of zinc chloride and ammonium chloride in certain specified proportions. It is claimed that this mixture has the advantage that the cells keep cleaner in use, the amount of crystalisation round the terminals of wet cells being appreciably reduced. The second main feature of the new edition is that, as regards the majority of the cells, the watt-hour outputs have been considerably increased, this having been made possible by the improvements in manufacturing technique that have been developed during the last two or three years, no doubt brought about by the very keen competition in this branch of the industry. A new method of testing has been introduced for the small-unit cells used for radio high-tension and grid bias batteries, pocket torches, &c., this being a light intermittent discharge through constant resistance.

A chart summarising all the dimensions, watt-hour outputs and test conditions, is given as an appendix. It can be detached from the specification and mounted in a convenient position for reference purposes in the test-room.

RELAYS FOR SIGNALLING.

Nos. 519 and 520—1933. These are the third and fourth specifications in the series of B.S. Specifications for Relays for Railway Signalling Purposes. These are No. 519, Tractive Armature D.C. Neutral-polar Line Relays, and No. 520, Alternating-current Track Relays. Further specifications in the series are at present under consideration.

These specifications are an endeavour to co-ordinate the rather diverse specifications which have hitherto been used by the various railway companies. Special features have in the past been called for, without, in many cases, due consideration being given to the possibility that these features merely add to the cost of the relay without any commensurate practical advantage being obtained. For example, some railways have considered it necessary to carry a number of different types of track relays to meet their requirements, whereas other railways have found it possible, and advantageous, to use a single type of relay for almost every conceivable kind of track circuit. All the British railway companies were represented on the Committee responsible for these specifications, and although non-standard relays will for some time to come be called for in certain cases, it is hoped that more and more uniformity will gradually be secured by the adoption of the standard specifications.

MR. J. D. DALLAS.—Mr. J. D. Dallas, chief mains engineer of the County of London Electric Supply Company, Ltd., is retiring at the end of the year, though his services will be retained in a consultative capacity. On Thursday evening, December 14th, a dinner was given to him at the St. Stephen's Club by a large number of the chief officials of the company, when he was presented with a gold cigarette case as a mark of the esteem and affection with which he is regarded.

WANDLE VALLEY SEWAGE DISPOSAL WORKS.—The contractors for the Wandle Valley sewage disposal works, described in last week's issue, included the following firms:—Structural work, William Moss and Sons, Ltd., Loughborough; filtering material, Hibberts, Ltd., Battersea, S.W.11; sludge pressing plant, Manlove, Alliot and Co., Ltd., Nottingham; sewage screening plant, S. S. Stott and Co., Manchester; flume recorder for storm water, the Lea Recorder Company, Ltd., Manchester; Venturi recorders for sewage, George Kent, Ltd., Luton; pumping plant, Pulsometer Engineering Company, Ltd., Reading; sewage distributors, Hartley, Sons and Co., Stoke-on-Trent.

Heat Transfer Between Metal Pipes and a Stream of Air.*

By EZER GRIFFITHS, D.Sc., F.R.S. and J. H. AWBERY, B.A. B.Sc.

Introduction.—When a stream of air has to be heated or cooled it is the common practice to pass the stream over the surface of a bank of piping through which is circulating a hot or a cold fluid. For cold storage work the cooling medium may be brine or a refrigerant such as ammonia, whilst for heating installations steam or hot water is used. The technical importance of data of the design of such appliances has resulted in a very large number of investigations being carried out in this field. All the earlier workers who attempted accurate measurements concerned themselves with observations of heat transfer between the fluid inside and that outside the pipe, thereby obtaining the total resistance to the heat flow. This coefficient is a complex one, for it is built up of the surface resistance between fluid and solid at each side of the dividing wall, as well as the resistance of the material of the wall. Recent workers on the subject, following Stanton, have tended towards a simplification of the problem by making a study of each of the fluid-solid resistances separately. The resistance of the wall itself can usually be calculated from a knowledge of the conductivity of the material, and so does not require independent measurement.

In the investigation now to be described, the authors have devoted attention solely to the transfer between the external surface of a pipe, usually constituting one of a bank, and the stream of air sweeping past, the transfer being reversed in direction according as the pipe is hotter or colder than the air. The data were required in the design of air cooling batteries for refrigeration work, but the conclusions arrived at are of general application in the design of heat transfer equipment.

Scope of the Experiments.—As stated above, a study has been made of pipes hotter than the air and of those colder than the air. In the latter case under certain conditions a layer of ice or snow forms on the surface. The greater part of the work has been concentrated on the study of pipes when arranged in banks, the individual pipes which constitute the bank being placed transverse to the air stream. It was not deemed necessary to study banks of piping when the axes of the pipes were parallel to the air stream, since a single longitudinal pipe should give the required information. When the pipe under study was longitudinal with the air stream, the successive elements of the pipe, starting from the point of contact of the air, were dealt with independently. A certain amount of attention was given to single pipes placed transverse to the stream, as this particular case had received study by numerous investigators in the past.

The pipe temperatures have ranged from about 90 deg. Cent. down to a few degrees below the freezing point of water, and the velocity of the air stream from about 30ft. per second (*i.e.*, 20 m.p.h.) down to free convection.

Description of the Wind Tunnel.—The experiments were made with the pipes installed in a closed circuit wind tunnel, shown in Fig. 1. The cross section of the tunnel was 2ft. high by 3ft. wide. A closed circuit type of tunnel was adopted because it was necessary to control the temperature and humidity of the circulating air. The working section of the tunnel was the upper one and was 4·5ft. in length. The air stream was maintained by an air screw coupled to a 5 H.P. motor of variable speed. The air from the screw was discharged into the lower section of the tunnel which contained the cooling coils, and, in addition, a heater for conditioning the air before it was delivered to the bank of piping under test in the upper section.

For adjustment of the humidity, trays of calcium chloride or water were inserted in the lower section of the tunnel. At the junction of the upper and lower sections, baffle plates were installed to ensure uniformity in the distribution of the air flow over the working section. As in all other tunnels, there was some degree of turbulence in the air stream.

The air velocity was measured by means of a Pitot tube and Chattock gauge. The Pitot head was generally situated a few inches in front of the pipe or the bank under test. Since the velocity is moderately uniform over the central area of the tunnel, it is immaterial where the actual measurement is made, provided it is in the neighbourhood of the pipe. When banks of pipes were under study the velocity was taken upstream from the bank at three or more vertical heights so selected as to give the correct mean.

Measurement of the Quantity of Heat.—The quantity of heat transferred from pipe to air or air to pipe was determined by two alternative methods:—(1) The dissipation of electrical energy in a heating coil; or (2) the change in temperature of a stream of liquid circulating in the pipe. The electrical method was applicable only in the case when the pipe was hotter than the air, whereas the circulating liquid was available when the pipe was hotter or colder than the air. The electrical method was the more convenient of the two.

The construction of an electrically heated pipe is illustrated in Fig. 2. A sheet of thin "micanite" was sprung into contact with the internal surface of the pipe, and the heater was made by winding "nichrome" strip longitudinally on the outside of a split ebonite tube, which, in turn, was sprung into contact with the micanite sheet.

When circulating liquid was used, two methods of construction were employed at different stages of the work. In the first, the liquid circulated through two spirals of small-bore tubing soldered to the internal surface of the pipe. The two spirals were wound together with their inlets at opposite ends of the pipe. Hence the gradient in temperature in the one due to the liquid flow was in the reverse direction to that in the other, so that the average temperature at any point would be constant along the length. Good thermal contact between the pipe and the spirals was secured by first soldering the spirals on the external surface of a pipe of smaller diameter than the experimental pipe, then inserting it into the latter, and filling the interspace with solder.

The other method of construction was to make a wooden plug which was a good fit in the pipe. This plug had longitudinal grooves cut in the surface, so that the oil circulated to and fro along the length of the pipe in contact with the internal surface. The details of the construction will be understood from Fig. 3. It might be anticipated that the longitudinal groove method of construction would result in a model having temperature variations along the length. Provided the liquid was flowing fairly rapidly so that it did not suffer a large temperature rise, the variations were found to be small.

With the circulating fluid type of model, a correction has to be taken into account for the work done in forcing the liquid through the pipe. To obtain this correction all that is necessary is to measure the pressure drop in the liquid as it passes through the model. The heat energy dissipated in overcoming this pressure is then equal to the mechanical energy lost, given by the product of pressure fall and rate of flow.

A tank containing a mixture of paraffin and lubricating oil was cooled by the spiral coil evaporator forming part of a refrigerating plant circuit. The temperature of this oil was maintained at the desired value by thermostatic control, using an immersion heater. The oil from the tank was pumped through the model whilst a glass vessel of known capacity was inserted in a by-pass in the return circuit. This was used to determine the rate of flow without altering the resistance of the circuit or allowing the oil to come into contact with the room atmosphere.

The temperature rise in the circulating liquid was measured by means of a five-way differential thermo-element, shown in Fig. 3. This thermo-element had an E.M.F. of about 200 microvolts per degree.

In the experiments on banks of pipes set transverse to the air stream, the pipes, whether heated electrically or by liquid circulation, were made 2ft. in length. Wooden extension pieces of the same diameter as the pipe were provided at each end. These extensions were 6in. in length, so that they just reached the side walls of the wind tunnel. By this arrangement the length of pipe under test was kept well within that portion of the air stream which had a uniform velocity. At the same time, those disturbances of the air flow were avoided which would arise if the pipes did not extend right aross the tunnel. This procedure did, however, introduce a source of heat loss or gain to the pipe which had to be allowed for, on account of the flow between the ends of the pipe and the wooden extension pieces. The magnitude of this correction was evaluated in the case of the electrically heated pipes by constructing a similar model to the normal ones, but with a 12in. length of wood replacing the centre 12in. of the model. Then if the heat loss per foot run from the metal pipe is H_1 and the flow from the pipe into one end piece is H_2, for a normal pipe the loss is $2\,H_1+2\,H_2$, since the pipe is 2ft. in length. For the special model, the heat loss is $H_1+4\,H_2$. By subtracting the former from twice the latter, a quantity is obtained which is three times the loss from a pair of ends, *i.e.*, three times the correction to be applied in an experiment with a normal pipe. For the pipe with liquid circulation the end correction was evaluated by making a comparison with an electrically heated pipe when both were swathed with cotton wool, in order to make the end loss as large a fraction as possible of the total.

Determination of the Specific Heat of the Oil.—In the experiments using pipes with liquid circulation, it was necessary to determine the specific heat of the oil used as the circulating medium. Two methods were used. At temperatures above the dew point of the air in the room, the usual calorimetric method was applicable, electrical energy being dissipated in a coil immersed in a quantity of oil and the temperature rise due to the heat input being measured. The heat capacity of the calorimeter and accessories was determined by carrying out a similar experiment using water in place of the oil.

In the other method the experimental pipe was utilised as a continuous flow calorimeter. A coil of nichrome wire was wound on the pipe and the whole lagged heavily with cotton wool. The pipe was then maintained cold by circulating oil through it and the temperature rise of the oil for various values of energy dissipated in the heating coil was measured. Experiments by this method at a mean temperature of −6 deg. Cent. gave a specific heat of 0·38 calorie per cubic centimetre per degree Centigrade for the oil mixture employed, whilst similar experiments at a temperature of +36 deg. Cent. gave 0·41 and 0·42 for the specific heat. The value at 16 deg. Cent., obtained by interpolation from these figures, is 0·40, and this is in good agreement with the value 0·394 found by experiments using the first method described above.

Measurement of the Temperature of the Surface of the Pipe.—The temperature of the pipe surface was obtained by means of copper-constantan thermo-elements. At the appropriate spot, plugs of copper and of constantan were riveted into the pipe surface and the tops of these filed off flush with the surface. Holes were drilled in the centres of these plugs and the copper and constantan wires attached by driving in taper plugs. The large area of contact between the plugs and the pipe ensured that the heat conduction along the leads did not cool the junction appreciably. As a general rule, five thermo-elements were used on each pipe under test, these being distributed equally along the length and arranged in spiral formation so as to give the temperature at points spaced around the circumference of the pipe.

[Here the authors proceed to present the results obtained from single pipes placed transversely to the air flow. Their method of presentation is founded on the principle of similitude. After considering various alternative possibilities from the point of view of dimensional theory, they deduce that $H/k\,\theta$ is a function of $V\,d/\nu$ and θ/θ_0, where H is the heat loss per unit time per unit length of pipe, k is the thermal conductivity of air, θ is the temperature excess (that is to say, the difference between the temperature of the air and that of the surface of the pipe), θ_0 is the temperature of the air, V is the velocity of the air, d is the external diameter of the pipe, and ν is the kinematic coefficient of viscosity of the air. Experiment, they say, shows that the effect of the variable θ/θ_0 is negligible. From this theoretical basis they ultimately develop the formula

$$H=V^{\frac{1}{2}}\,\theta\,(0{\cdot}36+0{\cdot}50\,d),$$

where H is the heat loss in B.Th.U. per foot run per hour, V the velocity of the air in feet per second, and θ is the temperature excess in degrees Centigrade. This formula, it is emphasised, is empirical, in spite of the theoretical considerations which led the authors to its establishment, and may not be applicable outside the range of their experiments. Nevertheless, it reproduces with fair accuracy the experimental figures obtained by the authors with single copper pipes of from 1¼in. to 3in. diameter, and with a single iron pipe, 1⅞in. in diameter.]

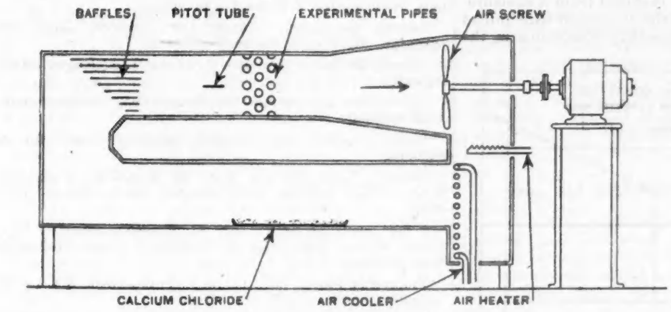

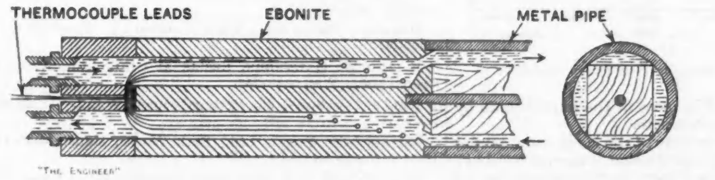

FIG. 1 (*Above*)—*Section Through Wind Tunnel.*
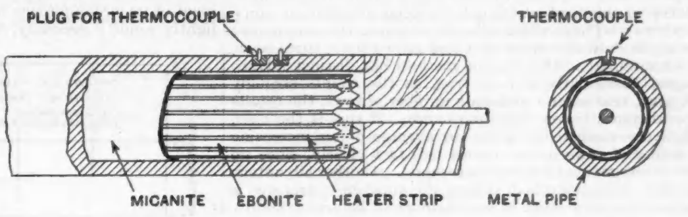
FIG. 3 (*Below*)—*Construction of Pipe for Liquid Circulation Method of Measuring Quantity of Heat.*



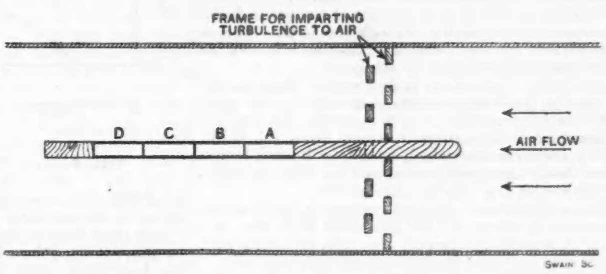


FIG. 2 (*Above*)—*Construction of Pipe for Electrical Method of Measuring Quantity of Heat.*
FIG. 4 (*Below*)—*Longitudinal Pipe in Tunnel.*

Pipe with Axis Lying Along the Air Stream.—A considerable number of the batteries for air cooling in use at the present day are of the longitudinal type. In these, the air stream flows through the battery in a direction parallel to the length of the pipes. Generally, the distance between the pipes is such that the section of the air stream associated with any one pipe is not affected by the presence of the adjacent pipes. Hence there is no necessity to study banks of piping when longitudinal formation is under consideration and a single pipe will give the essential information.

From general considerations it would be expected that the heat transfer coefficient would vary considerably from point to point along the pipe. The experimental model used for this work was therefore made with four separate 6in. sections, each having its own independently controlled electrical heater. To prevent heat conduction from one section to another, these were separated by wooden discs about ⅛in. thick, and the currents in the various sections were adjusted so that adjacent ends of different sections were at the same temperature. In consequence of the decreasing heat transfer, the temperature rose when proceeding downstream along any one section, so that the next section had to be at a higher mean temperature than the preceding one.

Upstream from the first section A, the model—Fig. 4—was provided with a fairing of wood, about 18in. long, having a hemispherical nose, so that the air should be flowing smoothly when it met the first heated section. The model was also prolonged by about 6in. of wood, made to extend beyond section D, so as to continue the flow pattern of the air to a point well away from the sections studied. The small heat flow into these wooden end sections was allowed for by calculation. Three thermocouples were pegged into each section and the effective temperature of the section was taken to be the mean of those given by the three.

The results found for section A are much higher than those for the later sections, and, furthermore, it is impossible to distinguish the points for sections C and D when the data are plotted on a graph. The ratio of the heat transfer coefficient for a transverse pipe to that for a longitudinal one varies with the section taken, and also with the Reynolds number at which the comparison is made, but it may be worth noting that the efficiency of the transverse pipe is of the order of twice that of a longitudinal one.

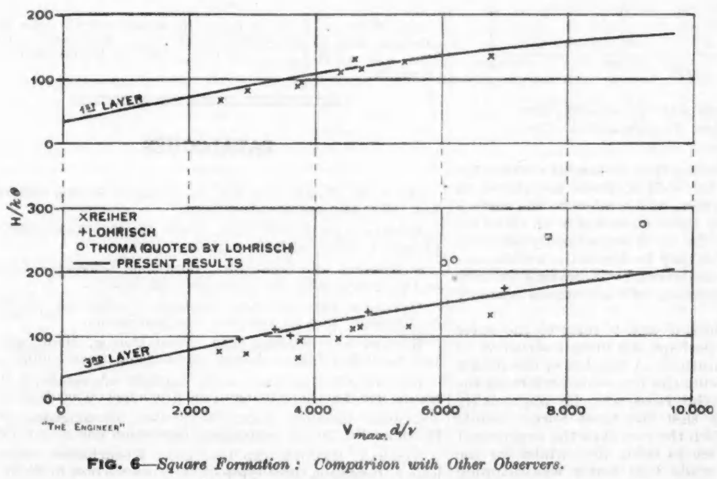

FIG. 6—*Square Formation: Comparison with Other Observers.*

Effect of Turbulence.—With a view to studying the increase in heat transmission due to a turbulent air stream, a state of eddy motion was set up by a framework of horizontal wooden laths placed in the wind tunnel, at a point between the baffles and the working sections of the longitudinal pipe, the general lay-out being seen in Fig. 4. The velocity observations were made in the space before the point where the air met the wooden fairing in the undisturbed part of the air stream. The greatest effect is in section A, for which the heat transfer is more than doubled. For section B, which initially had a smaller coefficient than section A, the increase is somewhat less than twofold, so that the disparity is increased. Similarly, sections C and D suffer still smaller increases. Although they had initially the same heat loss, yet in turbulent air section C loses more heat than D. The results, both with and without artificially induced turbulence, are consistent with the suggestion that the air, in travelling along the pipe, settles down to a constant state, and that increased turbulence tends to augment the heat loss.

Heat Transmission of a Pipe Constituting an Element in a Bank.—An important practical case occurs in pipes arranged in banks, the individual pipes having their axes transverse to the air stream. The number of different configurations which could be studied under this heading is almost unlimited, whilst theory gives practically no assistance in transferring the results obtained with one formation to that of any other.

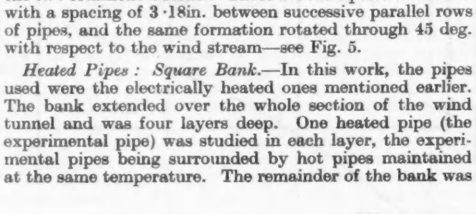

FIG. 5—*Formation of Banks.*

To keep the investigation within reasonable bounds, work on banks of pipes has therefore been restricted to the use of pipes of a diameter commonly used in refrigeration work, nominally 1$\frac{23}{32}$in. externally, built into banks of the two commonest forms. These are the square formation with a spacing of 3·18in. between successive parallel rows of pipes, and the same formation rotated through 45 deg. with respect to the wind stream—see Fig. 5.

Heated Pipes: Square Bank.—In this work, the pipes used were the electrically heated ones mentioned earlier. The bank extended over the whole section of the wind tunnel and was four layers deep. One heated pipe (the experimental pipe) was studied in each layer, the experimental pipes being surrounded by hot pipes maintained at the same temperature. The remainder of the bank was filled up with wooden dummies of the same diameter as the heated pipes.

The pipes were maintained at a series of steady temperatures and the energy dissipated in the heating coils measured for each excess temperature. The air speed was measured by means of a Pitot and static tube, which was traversed on the centre vertical line, about 15in. upstream from the first layer of pipes. In calculating the temperature excess for a pipe in a layer beyond the first, the air temperature is that prevailing at the later layer, and not the initial air temperature.

The results are most conveniently exhibited, as in Fig. 6, by plotting the two dimensionless variables $H/k\theta$ and Vd/ν. Not only does this method of representation enable the results to be applied to banks of the same form on a different scale, but it permits of heat transfer figures being taken for design purposes at any desired air temperature. For convenience in calculating heat quantities for any particular set of conditions from the curves, a table of values of ν and of k is inserted here:—

TABLE I.—*Kinematic Viscosity and Thermal Conductivity of Air.*

Mean temperature, deg. Cent.	Kinematic viscosity ν, C.G.S. units.	Thermal conductivity $k \times 10^5$, C.G.S.-calorie units.
—10	0·122	5·10
—5	0·127	5·25
0	0·132	5·32
5	0·136	5·40
10	0·140	5·48
15	0·145	5·56
20	0·150	5·64
25	0·155	5·71
30	0·159	5·78
35	0·164	5·85
40	0·169	5·93
45	0·174	6·00
50	0·179	6·08
55	0·184	6·15
60	0·190	6·23

The smoothed results taken from these curves are set out in Table II. below. In all cases, the actual observed heat transfer, corrected for the loss at the wooden ends of the experimental pipe, but not corrected for radiation, has been used. C.G.S. units are used throughout, but since both variables are dimensionless, any consistent set of units may be used with the figures.

TABLE II.—*Heat Transfer from Pipes in Square Array (Generalised Units).*

$\frac{Vd}{\nu}$	$H/k\theta$ (smoothed values).		
	Front layer.	Second layer.	Third layer.
0	49	49	49
2,000	115	128	128
4,000	168	195	195
6,000	216	259	259
8,000	261	320	320
10,000	307	382	382
12,000	343	441	442
14,000	377	494	494

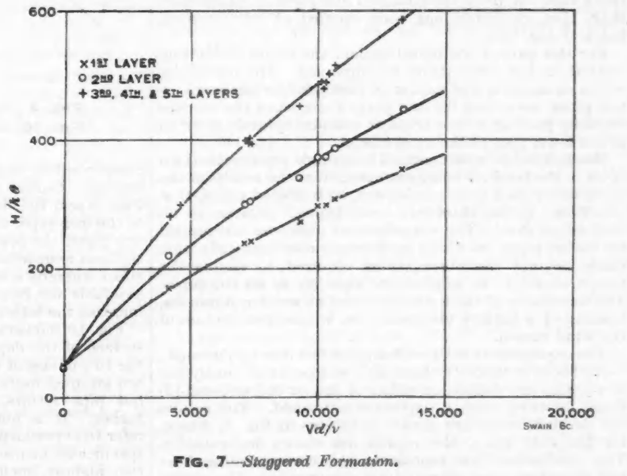

FIG. 7—*Staggered Formation.*

It will be seen from Table II. that the heat loss from a pipe in still air is independent of its position in the bank, and also that the loss in moving air increases a few per cent. in passing from the first layer to the second, but that this increase does not continue to the third layer. The most probable explanation is that eddies are either set up or increased in the air as it passes through the first layer, but that a steady regime is then reached. This evidence that eddy motion increases the heat transfer is not surprising, although it could not be predicted *a priori* what the extent of the increase would be.

Comparison of Results for Square Formation with those of Other Observers.—Table II. shows the heat loss from a pipe in each vertical row treated as an individual unit. Other methods of plotting have been adopted by some authors who have studied banks of pipes, the commonest being to show the mean heat loss in two rows, three rows, four rows, &c. The present method has distinct advantages, particularly if it is true, as the results strongly suggest, that after a moderate number of rows, the results for all pipes lie on the same curve. If this is the case, then the method of taking an average of an increasing number of rows never reveals this fact clearly, since no two averages ever become quite equal. Another advantage of the present method is that the total heat transfer is calculable for a bank of any number of layers by simply adding together the transfers for the individual layers. All that is necessary is to take account of the gradual rise in air temperature in passing through the bank. This is easily calculated, since the mass of air flowing is known, as well as the heat imparted to it in each layer.

It should also be noted, as stated earlier, that the air velocity used in these experiments in calculating the value of the Reynolds number ($V\,d/\nu$) is normally the velocity in the unimpeded air current upstream from the bank. This is the only velocity which would be known before hand when designing a bank, and indeed the only one which is measurable with any ease in actual practice.

No other authors have reported results for banks which are geometrically similar to the ones dealt with here, but it may be of interest to compare the present results with those published for other banks of square formation.†

Results for "Diagonal" or "Staggered" Formation.—The formation studied consisted of iron pipes of external diameter, $1\frac{23}{32}$in., arranged as in Fig. 5. Five layers in all were studied, this involving a bank of six layers so as to avoid anomalous conditions in the last one utilised. As before, the velocity was measured in the unobstructed air stream before it reached the bank of pipes, and the pipes were electrically heated. The results show a systematic increase in the heat loss in successive layers up to the third, after which it remains constant. A typical set of values of $H/k\,\theta$ at a fixed Reynolds number of 7220 is as follows:—

First layer.	Second layer.	Third layer.	Fourth layer.	Fifth layer.
243	302	394	400	397

Manifestly the experimental points for the last three layers cannot be plotted on one diagram without confusion, so that in Fig. 7 only the mean results for the last three layers are given. This figure shows the whole of the experimental results for this formation, when the pipes were hotter than the air The results found for the staggered formation suggest, even more than those for the square formation, that the air is set in a definite state of eddy motion in the first layer, and that the second layer adds to the general turbulence, the process being completed after the third layer. Similar results have been previously reported, in particular by Reiher in his study of single pipes. He succeeded in increasing the heat transfer by about 50 per cent. when the air falling on one of his pipes was first passed through a grid of piping to induce eddy motion.

It was considered of interest to examine the corresponding case when the air falling on the bank of pipes was artificially made turbulent. For this purpose the framework of wooden laths described previously was placed in the path of the air after it left the baffles at the entrance to the working section of the wind tunnel. The heat transfer in this case was very considerably augmented, and it is possible that the limit of increase in turbulence of the air stream was practically reached, since the second row lost hardly more heat than the first under these conditions. For each of them the heat transfer was greater when the framework was present than it was for the last layers in the absence of the framework. The effect due to the presence of the framework represents an increase of about 100 per cent. for the first layer and about 50 per cent. for the second.

Pipes below 0 deg. Cent.: Staggered Formation.—The diagonal formation of transverse pipes, besides being the one which shows the highest efficiency, is also the one commonly used in refrigeration practice. Consequently, this formation, using the standard iron pipes of rather more than $1\frac{7}{8}$in. diameter, has been studied at temperatures below 0 deg. Cent.

For this part of the investigation, the liquid circulation method had of necessity to be employed. The remainder of the equipment was similar to that used for the work on hot pipes, save that for one part of the work the air was dried by passing it over trays of calcium chloride inserted in the lower part of the wind tunnel.

Measurements were confined to a single pipe in the third layer of the bank, it being assumed, from the results of the work which had been carried out with heated pipes, that conditions in the third row were typical of those in all succeeding rows. The experimental pipe was surrounded by cooled pipes on which no thermal measurements were made beyond the observations required to enable the temperatures to be adjusted to equality in all the pipes. The remainder of the bank consisted of wooden dummies, making up a battery occupying the whole cross section of the wind tunnel.

The experiments with cooled pipes fall into two groups:—(1) Those in which the humidity was kept sufficiently low to prevent any deposition either of dew or of frost, and (2) those in which such a deposit was formed. The results for the first group are shown as crosses in Fig. 8, where, for the cold pipes, the results are shown individually. The continuous line represents the corresponding heat loss from hot pipes as measured electrically. The circles represent a few further observations made on hot pipes by the liquid circulation method. They serve to illustrate the order of agreement between the results obtained by the two methods.

When it is remembered that radiation is somewhat less at the lower mean temperatures, the results shown in Fig. 8 justify the conclusion that, within experimental error, a change in the direction of the heat transfer alters only the sign of $H/k\,\theta$, and not its actual magnitude.

In the experiments in which a snow or ice deposit was formed, two additional measurements were made. First, the thickness of the deposit was deduced from a measurement of its circumference by means of a paper tape pulled lightly round; secondly, the humidity conditions in the wind tunnel were recorded in most of the experiments by means of an Assmann psychrometer.

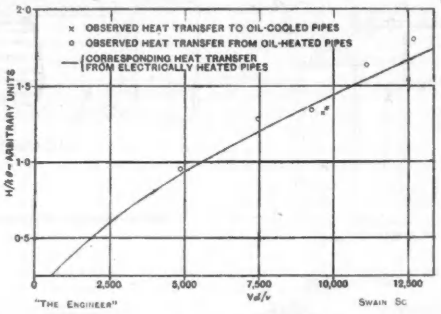

FIG. 8—*Heat Transfer for Dry Pipes (Cold).*

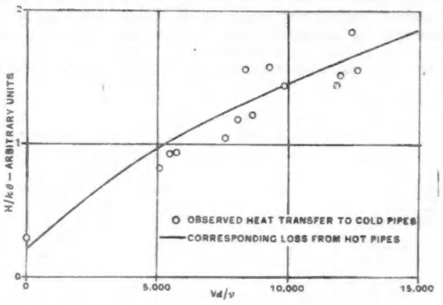
It is clear that the temperature of the ice or snow cannot be above 0 deg. Cent., and equally that it cannot be above the hoar frost point, since otherwise the deposit would not form. If it is below the hoar frost point, then the deposit will continue to build up, and will increase in thickness until this temperature is reached at the outer surface. In equilibrium, the temperature of the latter must therefore always be either 0 deg. Cent. or the hoar frost temperature, whichever is lower, whereas it will be below the stated value if equilibrium has not been reached.

The dimensionless variables may be tabulated in two ways. First, the measured temperature of the pipe surface may be used in the formula $H/k\,\theta$, the external diameter of the pipe itself being then used in the corresponding formula $V\,d/\nu$. Secondly, the estimated temperature of the outside of the ice or snow deposit may be used, the corresponding value of *d* being that measured outside the deposit. Curves plotted by both methods are shown in Figs. 9 and 10. In the former, which refers to the surface of the iron pipe, the results agree quite well with those for dry pipes, the presence of the ice or snow hardly affecting the heat transmission. This may be due to the well-known effect whereby a layer of insulation, by increasing the area available for heat transmission, will sometimes actually increase the latter.



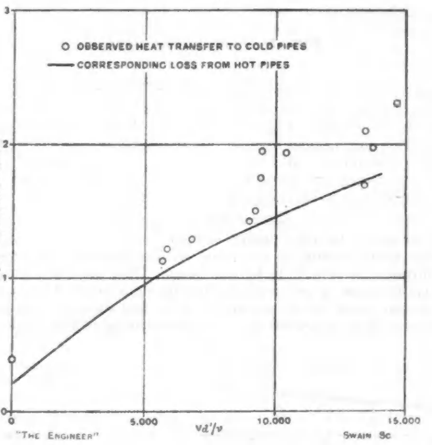


FIG. 9 (*Above*)—*Heat Transfer to Cold Pipes.*
FIG. 10 (*Below*)—*Heat Transfer to Cold Pipes.*

Fig. 10, however, in which d' and θ' refer to the outer surface of the deposit, is perhaps the more instructive of the two modes of representation. A number of the results are grouped quite well about the line which refers to the hot pipe results, whilst the remainder lie appreciably higher. It is noteworthy that the three lowest results refer to experiments in which the record of the experiment specifically mentions the ice as being dry, whilst for the two highest, mention is made that water was dripping from the pipe. This water in condensing from the atmosphere would liberate a considerable amount of latent heat, and evidently this is the cause of the high rate of heat transfer. It is clearly desirable in practice to aim at this condition, which can increase the heat transfer by about 30 per cent., *i.e.*, an increase which would require 50 per cent. increase in air velocity to attain.

---

† This comparison is exhibited in Fig. 6, but the original paper should be consulted for information concerning the extent to which the different investigators' figures are really comparable.—Ed., The E.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

Mr. A. R. Cooper, chief engineer of the London Passenger Transport Board, has been unanimously elected chairman of the Civil Engineers' Committee of the Railway Clearing House for the year 1934.

Marshall, Sons and Co., Ltd., of Gainsborough, inform us that on and after January 1st, 1934, their offices will be at Brettenham House, Lancaster-place, Strand, London, W.C.2 (phone, Temple Bar 5792 and 5793).

Mr. E. W. Hudson, solicitor to the Electricity Commission since shortly after its inception in 1919, is severing his connection with Savoy-court as from January 1st. We understand that Mr. Hudson has found his combined work, on behalf of the Commission and the Ministry of Transport, too exacting, and that he intends to resume private practice.

Sir James Milne, C.S.I., general manager of the Great Western Railway, has been unanimously elected chairman of the Railway General Managers' Conference for the year 1934. Sir James, who has been general manager of the Great Western since 1929, was for a time Director of Statistics of the Ministry of Transport on the formation of the Ministry, but returned to the Great Western Company in 1922.

CONTRACTS AND ORDERS.

The Editor is always happy to print short announcements of contracts and orders in this column provided they are sent to him in time to have news value and that they are likely to interest readers.

Henry Robb, Ltd., of Leith, have received an order for a coasting barge to carry 125 tons of cargo. The vessel is to be fitted with a 2 H 4 type, 100 B.H.P. British Kromhout marine oil engine.

CATALOGUES.

Sir W. H. Bailey and Co., Ltd., Albion Works, Salford.—List 733 of coin-operated turnstiles.

Mather and Platt, Ltd., Park Works, Manchester.—A pamphlet dealing with the canning of peas.

S. Russell and Sons, Ltd., Bath-lane, Leicester.—Leaflets on the various alloy cast irons made by the firm.

Davidson and Co., Ltd., Belfast.—Publication S F 88 B., on "Aeroto" fans for auxiliary mine ventilation.

Holden and Brooke, Ltd., West Gorton, Manchester.—List No. 909 of "Quick Access" split casing design pumps.

Ruston and Hornsby, Ltd., Lincoln.—A catalogue illustrating and describing in detail the firm's fuel oil locomotives.

George Ellison, Ltd., Perry Bar, Birmingham, 20.—Brochure No. 204 on switchgear installation and maintenance.

Newman, Hender and Co., Ltd., Woodchester, Glos.—A leaflet illustrating three types of valve wheels now made by the firm.

Jointless Firebrick Company, Ltd., 170, Piccadilly, W.1.—A leaflet illustrating the "Plibrico" observation port for furnaces.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

Import and Export Figures.

The Board of Trade import and export figures for November are again encouraging so far as the British iron and steel trades are concerned. The total imports of iron, steel, and manufactures thereof, increased from 88,854 tons in October, to 91,327 tons in November, whilst the exports were down a little to 184,391 tons in November, compared with 193,613 tons in October. For the eleven months ending November 30th, the imports totalled 880,856 tons, and the exports 1,750,399 tons. The imports of pig iron remained insignificant, amounting in all to 2185 tons of foundry iron, of which 1306 tons came from India, and 835 tons from Sweden. The imports of basic iron were 8090 tons, all of which came from India. It is interesting to note that the importation of semi-finished steel, such as blooms, billets, and slabs, after increasing for two months, declined in November to 21,308 tons from 28,511 tons in October. No doubt this was partly due to the restrictions of offers from the Continent. The principal suppliers of this material were Belgium, 12,473 tons, and France, 5583 tons. There was also a decline in the quantity of sheet bars imported, the figure for November being 7850 tons, compared with 8626 tons in October. The imports of beams, girders, and joists, after declining for two months, showed an increase in November to 6936 tons, compared with 4487 tons in October. The imports of hoop and strip, which had increased from 8668 tons in September to 9934 tons in October, fell in November to 7362 tons. On the export side the quantity of pig iron dispatched overseas reached 13,998 tons, which was a sharp increase over the October total of 7559 tons. The general exports of steel reached 108,132 tons, the largest buyers being India, 24,582 tons, and British South Africa, 11,526 tons. Exports of plates and sheets, not galvanised, reached 9547 tons, of which Canada took 1681 tons. The exports of plates and sheets under ⅛in. thick, totalled 10,005 tons, of which 2338 tons went to India, 1770 tons to Australia, and 1633 to the Argentine. The exports of galvanised sheets were disappointing, and reached only 23,461 tons ; but the exports of tin-plates were maintained at 40,435 tons. The total railway material exported in November was 9433 tons.

Machinery Exports.

The exports of machinery during November increased in tonnage, but declined slightly in value compared with October. The tonnage reached 27,937 tons, against 25,142 tons in October, whilst the value amounted to £2,482,702, compared with £2,509,603 in October. The exports of textile machinery amounted in value to £490,480, compared with £475,670 for the previous month. British India was the largest individual purchaser, taking goods to the value of £130,141. The exports to Germany were valued at £20,122, and to Holland at £22,329. The export of prime movers decreased in value during November to £255,230 from £266,577. Of this total the exports to India reached £33,711 ; those to South Africa £29,217, and to Australia £10,363. The value of the exports of machinery and parts thereof improved to £51,599, against £47,030 in October. Countries in Europe purchased to the value of £9872, and countries in America to £8179, the exports to British India amounting to £6143. Exports of machine tools for metal working showed a notable improvement in November to £101,983, compared with £74,625 in the previous month. The largest individual buyer was Soviet Russia, which purchased machinery to the value of £18,123, British India coming next with purchases to the value of £15,964. The exports to European countries, excluding Russia, amounted to £23,177. The export figures included also three steam vessels having a gross tonnage of 7949 tons, valued at £118,930, and eleven motor vessels of 699 tons gross, valued at £25,587.

The Pig Iron Market.

It is many years since the situation of the Cleveland pig iron producers was so favourable. In fact, something like a famine in foundry iron prevails in that district. The stocks in makers' hands are sold and the forward sales already made will absorb the current output for a month or two ahead. At the same time, the requirements of the market are increasing and so acute has the position become that local consumers have been obliged to import supplies of Northants iron. It is expected that the make of Cleveland foundry will be increased early in the New Year ; but so far there has been no announcement on this point. The attitude of the makers is somewhat puzzling and although there are buyers willing to contract for delivery as far forward as June, producers appear reluctant to enter into any engagement. This, it is thought, points to an increase in prices within the next few weeks ; but possibly the price for Cleveland will not be advanced until the makers in other districts are in a position to raise their prices. The demand for Midland irons is well maintained, but stocks have not been depleted to the same extent as on the North-East Coast. Nevertheless, the makers' position has improved sufficiently to enable them to adopt a rather stiff attitude to consumers. Most of the large buyers of Midland irons have covered their requirements, but there is a steady business passing in small tonnages for immediate delivery. The shortage of Cleveland iron has benefited makers in this district, and they have effected fair sales to consumers on the North-East Coast and increased the quantities dispatched to the Scottish light castings industry. The situation in the market for hematite has also become tight. The producers are well sold over the first few months of next year and stocks, which have been much reduced during the past month or two, are being drawn upon at an increasing rate. The stoppage of two furnaces at the Normanby Works was followed by the lighting of one at Consett. It is anticipated that another furnace will be put on to produce hematite early in January. Merchants hold fair quantities, but as an advance in prices is thought possible within the next few weeks, they are not prepared to accept lower figures than the makers. The position is not so good in Scotland, and some of the local make is being put into stock. The demand from the light castings industry is steady. Ten furnaces are in operation in Scotland, of which six are producing foundry, three hematite, and one basic.

Iron and Steel Production.

The great improvement in the situation in the British iron and steel trades is shown by the monthly statement of the National Federation of Iron and Steel Manufacturers on the production of iron and steel during November. At the end of the month seventy-nine furnaces were in blast, which was an increase of five since the beginning of November. Although the report does not give particulars of these five furnaces, two were put into operation by Dorman, Long and Co., Ltd., one by the Frodingham Iron and Steel Company, Ltd., one by the Darwen and Mostyn Iron Company, Ltd., and one by Alfred Hickman, Ltd. The production of pig iron in November amounted to 374,900 tons, compared with 373,300 tons in October, and 267,700 tons in November, 1932 ; the daily rate of operation thus showed an increase of nearly 4 per cent. between October and November. The production included 102,400 tons of hematite, 178,300 tons of basic, 77,600 tons of foundry, and 9600 tons of forge pig iron. The output of steel ingots and castings in November was 695,000 tons, compared with 668,300 tons in October, and 473,800 tons in November last year.

North-East Coast and Yorkshire.

Recently there has been a considerable increase in the output of finished steel materials on the North-East Coast, but so strong is the demand that it is expected fresh plant will be put into operation early in the New Year. The market takes a cheerful view of the position and there seems no anticipation of any decline in business beyond the usual fluctuations. The improved prospects in the shipbuilding industry and the expectation that fresh railway orders will be distributed in the New Year is the principal cause of this optimism ; but the strength of the current demand for sections, bars and structural material generally supports this view. Export business, although it has picked up a little lately, still lags, and the great bulk of the business transacted is on home account. The sheet mills are not so well employed as other branches of the industry ; but business with home consumers is steady. There has been no change in prices, but the quotations for some of the descriptions of uncontrolled steel material show a tendency to advance. In Yorkshire busy conditions rule in the iron and steel trades and an additional open-hearth steel furnace has been lighted at the Templeborough works of the United Steel Companies. This makes ten furnaces in commission at these works. The works producing axles, tires, and springs are busy and the demand for alloy and special steels is on a good scale. All the Sheffield re-rolling works are actively engaged, principally upon small bars and sections. A feature of the position is the strong pressure for immediate and near delivery. Recently business in boiler plates has expended, and the heavy engineering and electrical engineering industries are also taking good quantities of steel material.

Scotland and Lancashire.

The approach of the holidays has naturally caused some relaxation in the demand, but industrial operations have increased owing to the pressure of consumers to obtain deliveries before Christmas. It is not expected that the Scottish steel works will commence work upon materials required in connection with the recent shipbuilding and other contracts until after the holidays ; but the prospects of the industry have been greatly improved by the orders which have been given out recently. The certainty of work being re-started on the great Cunarder has naturally created a feeling of optimism in the steel industry, although most of the material needed for the completion of this vessel will consist of the lighter descriptions of steel. For the time being business in ship plates and sections is rather quiet. The amount of work received from structural engineers also is disappointing, and the tendency noticeable a few weeks ago for trading to expand in this branch has not been maintained. The tube works are busy on the Palestine pipe line order, which it is estimated will involve the use of from 5000 tons to 6000 tons of steel. The rail mills also are fairly busy on orders from China and India, and a contract has been secured for the supply of rolls for the new steel works in Pretoria. In Lancashire the steel industry is fairly well employed, but recently orders from the structural engineering shops have declined, although there are prospects of some improvement in this direction in the New Year. Similar anticipations are held by the plate manufacturers, who expect to benefit from the orders given out to the locomotive builders by the railways. The lighter sections of the trade are busy, and in some instances the works are operating almost at capacity. It is interesting to note that in this district little interest is shown in imported steel materials. Most users of bars, for instance, are still able to specify against contracts which were placed when the price for British re-rolled steel was much lower than to-day.

The Midlands.

Conditions in the Midlands reflect the approach of the holidays. The works are hastening to complete deliveries before closing down, and consumers are disinclined to place fresh business for the time being. There is no doubt that the works will enter the New Year with better order books than for many years past. The Midland constructional engineers, on the whole, are not busy, but there are a few exceptions to this rule. The sheet trade is well employed, principally upon the thinner gauges, and the works producing strip, in several instances, are behind hand in delivery, this being one of the best employed branches of the industry in the country. The re-rollers are also actively engaged upon the production of small bars, and business in this department seems likely to continue active right up to the commencement of the holidays. There has been no change in prices, the British works are still quoting £7 5s. to £7 10s. d/d, although there are more works asking the higher figure than was the case a week or two ago. Continental material is being offered at £6 10s. 6d. d/d, and if more orders are being placed with Continental sellers than has been the case for some months, the total volume of this business is not sufficient to cause the British makers anxiety. The steel works are quoting £7 15s. up to £8 5s. for bars, according to quality. Business in colliery steel still hangs fire somewhat, although it is increasing and prices are firmer. Similarly, purchases of bright drawn steel have fallen off, but this is scarcely surprising, considering the strong demand for this material during the past two months.

A South African Contract.

Tenders are being called for by the City Council of Pretoria for an important extension of the municipal power station. The object of this extension is to provide for the extra power which will be required to operate the national iron and steel works which have been established at Pretoria. These works are expected to begin operations within the next few weeks. The Iron and Steel Corporation will supply power from its own station, but it will draw a supplementary supply from the municipal station to meet the needs of a galvanised sheet works which it has been decided to establish in addition to the main steel works. The iron and steel works have been erected mainly by British contractors, and it is estimated that by the time the scheme is completed the capital expenditure will amount to £6,000,000. The intention is to manufacture 150,000 tons of steel per annum. The Town Clerk of Pretoria (Mr. M. G. Nicolson) and the City Electrical Engineer (Mr. L. L. Horrell) are on a visit to this country, and have been arranging the details of these power station extensions with Merz and McLellan, the Council's consulting engineers.

Copper and Tin.

It not infrequently happens that at the end of the year a sharp rise takes place in the prices of non-ferrous metals. This is partly due to consumers covering their requirements for the early part of the New Year, and perhaps to a certain amount of manipulation, since higher prices at the turn of the year give balance sheets a rather better appearance. This year, however, the movement seems to be a natural outcome of an increase in buying. The German consumers have purchased fair quantities, and in the United States also the demand has improved probably in the belief that the "code" will come into force in the New Year and prices will be automatically increased. The British users of copper have also shown more interest in the market. In America the price has increased to 8.25 c. to 8.37½ c., and the export price has advanced from 8c. to 8.25 c. to 8.37½ c., the sterling quotations ranging between £35 10s. and £37 c.i.f., according to the exchange. Business in the standard market has been better, and prices have advanced in sympathy with the electrolytic quotation, and a fair amount of speculative buying. . . . In the tin market there has been little change in values. Business has been quiet, and few transactions with the United States have occurred. European consumers also have shown only a slight interest in the market. It is suggested that the Pool has sold good quantities of tin to the United States, but the market there has not had an active appearance. In fact, the tin market seems to have settled down for the time being to rather uninteresting conditions, which will probably rule until well into the New Year. It is anticipated that there will be another decrease in the visible supply at the end of March.

Lead and Spelter.

Prices in the lead market have remained steady, but trading has been rather quieter than of late. Nevertheless, good quantities of lead are still passing into consumption. It is not expected that the strike at the Mount Isa Mine will last long, but this has had no influence upon the market. Some surprise was occasioned when it was found that the Australian shipment of lead to Europe during November was the largest for any month during the year, the total reaching 18,200 tons. The Burmese shipments were also fairly large at 5000 tons. It is obvious, therefore, that there is plenty of lead available for the market. The demand for lead in Germany is said to be improving, largely as a result of the public schemes which have been undertaken in that country. . . . In the spelter market prices, after showing some weakness, have developed a stronger tendency. Consumers have bought sparingly, but there has been a steady stream of business which augurs well for trade in the New Year. The statistical position seems to be improving, and the announcement of the renewal of the Cartel has been favourably received. The statement issued after the Cartel meeting last week that during November stocks had fallen by about 2000 tons, and that the total stocks were about 128,000 tons, or, roughly speaking, about two months' supply, disclosed a better position than the market had anticipated. If the Continental consumption increases in the New Year as seems to be expected, the position of this market should be materially strengthened.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Tax on Foreign Labour.

The insertion of a clause in the Budget to impose a tax of 10 and 15 per cent. on the wages paid to foreigners, according to whether they occupy sedentary positions or are engaged in manual labour, complicates still further the problem of foreign workers who were imported in huge numbers during a period of industrial activity and are still employed on a much smaller scale in certain industries where French labour is not available. It is not certain yet whether the tax will be withdrawn before the final adoption of the Budget, in view of the opposition of employers and the difficulty of reconciling it with treaty obligations, but the suggestion that such a tax should be imposed shows clearly the change that has taken place in the industrial situation during the past four years. Prior to that period the demand for labour to meet a rapidly growing industrial development could only be satisfied by a large importation of men from Poland and other countries by means of a State organisation which supplied employers with men under conditions that placed them on exactly the same footing as French workers as regarded wages and social advantages. When the slump came men returned to their respective countries, and in three years about a million of them left, so that the problem of unemployment did not affect the country until last year. To-day the number of French workers receiving relief is steadily increasing, despite the departure of foreigners at the rate of from 700 to 800 a week. While the tax on foreign labour aims at bringing in fresh revenue, it is also intended to compel employers to extend the preference for French labour beyond the obligation already imposed upon them to employ only a stated percentage of foreign labour. Unfortunately for employers, this is not always possible, for in the north Belgians and Poles are engaged in coal mines, in mills and forges and other industries on work that the French are generally reluctant to undertake or of which they have not the same experience as foreigners, while from Marseilles there are strong protests against a tax which will seriously affect industries carried on almost entirely with Italian and other foreign labour. The tax will make a perilous addition to production costs. The difficulties raised by recent legislation regarding foreign labour reveal the anomalous position of some French industries which are dependent on foreign workers. In the event of a general industrial revival those industries may be placed in a serious situation unless French labour adapts itself to a class of work that is at present carried on mainly by foreigners.

Coal.

The demand for domestic coal has increased so largely during the present cold spell that the import quotas for January have been applied to the second half of the present month. At the same time the miners in the Nord and the Pas de Calais have made a further urgent appeal to the Government to take immediate steps for the relief of their unemployed. They want the Government to levy a tax on the coal brought to bank at the French collieries for the creation of a relief fund. The Minister of Public Works explained that he had already reduced the import quotas by 10 per cent. and had provided facilities for the transport of French coal in French ships to the coastal ports, but these remedies have obviously done little to alleviate the situation of the coal industry, for the reason principally that it does not produce steam coal of the quality required at the ports and also because, at a time when there is a heavy demand for other than industrial fuels, the canals are frozen and considerable quantities of coal are unable to be moved. In view of the slump in industrial coal the colliery companies are making great efforts to supply a domestic demand with composite fuels and semi-coke, which latter must be disposed of if the low temperature treatment of coal is to make any headway, and the companies are able to solve the difficult problem of making oil production commercially successful, but notwithstanding satisfactory technical results, and an increasing output of ammoniacal products, the situation of the industry is still affirmed by coalowners to be imperilled by foreign competition. Now that there is a heavier demand for domestic fuels more coal has to be imported.

The Surtax.

The Minister of Commerce, Monsieur Laurent Eynac, has confirmed in a statement made to the Parliamentary Customs Commission that the Government has prepared a decree suppressing the surtax on British goods, and he stated that an assurance had been given to Mr. Runciman which enabled the British Minister to suspend the application of the reprisal tax on French goods until the decree could be published and the law instituting the turnover tax repealed. Monsieur Eynac affirmed that this will be done towards the end of the month, and he held out the hope that a treaty of commerce between the two countries will be signed in the course of the ensuing few months. After the French Minister had described the disastrous boomerang effects of the surtax upon exporting industries the Commission left the Government with a free hand to carry out negotiations with Great Britain.

Air Organisation.

After suppressing the dual control of military and naval aviation and placing it directly under the Air Ministry and dividing the country up into zones with organisations for coast and frontier defence, the Air Minister proceeded with a reform of civil aviation by the fusion of the five air transport companies into one company. He has continued the reform of simplifying the organisation by authorising Chambers of Commerce to create and control air ports. Those in the districts of Paris, Lyons, Bordeaux and Marseilles will be made autonomous under the administration of the respective Chambers of Commerce. The State has therefore accepted the principle of private initiative in the laying out of landing grounds and promoting national air services with the approval of the State, and, judging from the number of plans that have been put forward from time to time, it appears likely that national air transport will enter upon a new phase, though occasional experimental working has shown that it has limitations.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office, Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

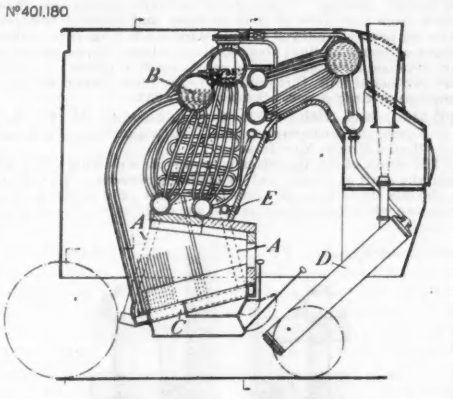
The date first given is the date of application ; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

STEAM GENERATORS.

401,180. April 10th, 1933.—Water-tube Boilers for Steam Wagons, Maschinenfabrik Esslingen, Esslingen-on-Neckar, Wurtemburg, Germany, and O. Gunther, 30, Mettinger Strasse, Esslingen-on-Neckar.

This remarkable boiler is put forward as being specially suitable for steam wagons and light locomotives on account of its compactness. Although the complicated system of water tubes and superheater is described in detail in the specification, the chief claim is for the arrangement of the down-comer tubes A A in the form of a triangle in order to transmit inertia forces, caused by the acceleration and braking of the vehicle, from the drum B to the foundation ring C, and thence to the frame of the vehicle. D is a feed-water heater and E the steam outlet.—*November 9th*, 1933.

Nº401,180

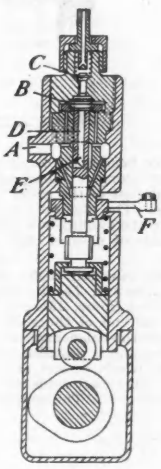


INTERNAL COMBUSTION ENGINES.

401,171. March 20th, 1933.—Fuel Pumps, H. L'Orange Feuerbacherweg 19, Stuttgart, Germany, and Simms Motor Units, Ltd., Percy-buildings, Gresse-street, Rathbone-place, London, W.1.

This fuel pump is of the fixed stroke type and its delivery is regulated by by-passing back to the suction. The suction inlet is shown at A and the suction valve, which is of the plate type, at B. The delivery valve is marked C. Governing is effected by the port D in the plunger registering, more or less, with a helical face E on the inlet port, according to the extent to which the plunger is turned by the crank F.—*November 9th*, 1933.

Nº401,171

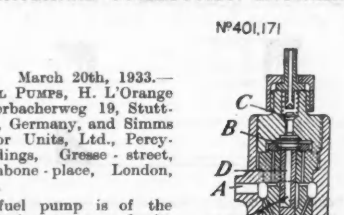


DYNAMOS AND MOTORS.

400,957. May 2nd, 1932.—Dynamo-electric Machines, the British Thomson-Houston Company, Ltd., Crown House, Aldwych, London, W.C.2, and Arthur Hemborough Maggs, of "The Briars," Wellsway, Keynsham, near Bristol.

This invention relates to rotating bodies subject to pulsating torque. An object of the invention is to balance the effects of the pulsations in the torque and so to reduce torsional vibrations in the body. The rotating shaft A transmits a load torque, and is also subject to pulsating torque. It may be the shaft of a dynamo-electric machine in which pulsations of torque are produced ; for example, in certain types of single-phase dynamo-electric machines pulsations of torque occur at twice the frequency of supply. The boss B is mounted on the shaft, and an annular mass C is supported concentrically thereon by spring members D giving torsional resilience with low damping. The invention is particularly applicable to lift drives. Pulsating torque results in humming noise in the cage, and it is found that this may be eliminated by the application of the invention. A single device according to the invention will only balance the effects of pulsating torque of one frequency. If a rotating body is subject to pulsating torques of several definite frequencies, each may be balanced by a separate device according to the invention.—*November 2nd*, 1933.

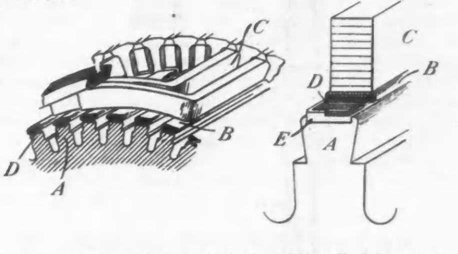
Nº400,957



401,009. May 9th, 1932.—Windings of Dynamo-electric Machines, International General Electric Company Incorporated, of 120, Broadway, New York, U.S.A.

A scheme is described in this specification for allowing the end windings of electrical machines freely to expand, the invention being particularly applicable to long machines. The rotor end is provided with teeth A. Bars B are arranged over the teeth on which the end windings C lie. Each bar covers a roller bed filled with steel rollers D of small diameter over the peripheral surfaces of the teeth. The roller path on the tops of the teeth is formed by way of example as a box-shaped holder E, so that the rollers are guided and secured against lateral deviations from their path. It is fastened on the tops of the teeth in any suitable manner.—*November 9th*, 1933.

Nº401,009

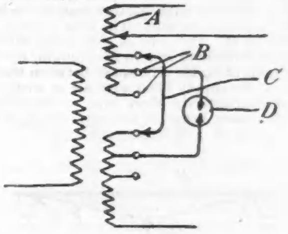


TRANSFORMERS AND CONVERTERS.

400,962. May 3rd, 1932.—On-load Tap-changing Arrangements for Electric Transformers, the British Thomson-Houston Company, Ltd., of Crown House, Aldwych, London, W.C.2, and Charles Gilbert Mayo, of 17, Alexandra-road, Rugby.

The object of this invention is to provide an on-load transformer tap-changing equipment arrangement whereby the switching connections are greatly simplified while still obtaining the advantages of the complicated switching connections heretofore employed. The diagram shows a transformer having a secondary winding A divided into two sections, adjacent ends of which are provided with taps B arranged for connection by a movable bridging member C. In order to prevent the secondary circuit from being interrupted when the bridging member is moved from one tap to an adjacent tap, a gas discharge tube D is connected, as shown, the breakdown voltage of which is such that no current normally passes it. When, during tap-changing operations, the bridging contact is initially separated from a tap, the voltage across the tube D rises to a value sufficient to cause current to flow through the tube, and thus undue sparking at the taps is prevented. When the tap-changing operation is completed, the tube returns to its normal non-conductive state.—*November 3rd*, 1933.

Nº400,962



TRANSMISSION OF POWER.

400,235. March 17th, 1932.—Insulated Electrical Cables, Johnson and Phillips, Ltd., of Charlton Park, S.E.7; Albert Periam Pyne, of 7, Kidbrook Park-road, Blackheath, London, S.E.3 : and Tom Bond Parker, of 30, Repton-road, Orpington, Kent.

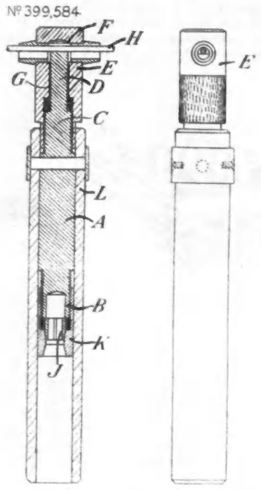
The di-electric or covering applied to electrical cables usually contain ingredients of an inflammable nature. This applies particularly to the insulation of paper-insulated cables, which consists of lappings of thin paper tapes saturated with impregnating compound, such as mineral oil, having a considerable resin content. This inflammability is frequently very inconvenient, as, for example, when a fault is being burnt out in a cable laid in a duct. On such occasions the di-electric or cover of the cable frequently burns along the duct for many yards in each direction from the fault. It is the primary object of this invention to provide improved means whereby the inflammable material of a cable di-electric or cover will be prevented from burning and the invention consists broadly in the arrangement that the covering includes a layer of fibrous material impregnated with a non-inflammable chlorinated naphthalene, which, on the application of heat, generates combustion-resisting gas, the layer not being otherwise treated with flame-resisting compound. In the case of the paper-insulated cables the paper may be impregnated with poly-chlorinated naphthalene in place of the usual compound, either before or after application to the cable. It is found that insulation so impregnated cannot be ignited, or if the application of heat be intense enough to char or burn the papers, such burning or charring will be only local, and will cease immediately the source of heat is removed. A further advantage of such insulation is that, should a cable break down, the effects will be felt to a less extent on surrounding cables, since the gases generated from the impregnating compound by the arc will tend to damp it out quickly.—*October* 17th, 1933.

WELDING.

399,584. April 28th, 1932.—Electrode Holder for Use in Electric Arc Welding, Bernard Wasley Rowe, of 290, Derbyshire-lane West, Stretford, Manchester, and Associated Electrical Industries, Ltd., of Crown House, Aldwych, in the City of Westminster.

The welding electrode holder described in this specification comprises a body portion A of copper or steel having reduced portions at each end. The reduced portion B at the lower end is screw-threaded and the reduced portion C at the upper end is also screw-threaded, the upper part of the latter portion being reduced in diameter to constitute a plunger D. The lower screwed portion accommodates means whereby the current-carrying cable for the tool is attached, and the portions C and D serve for the accommodation of the device for gripping the electrode. The electrode-gripping device comprises a metal bar E, which is drilled with a transverse hole F near its upper end. An axial hole G extending from the lower end of the bar and slightly greater in diameter than the diameter of the plunger D on the holder A communicates at its upper end with the transverse hole F. At its lower end the axial hole G is increased in diameter and internally screw-threaded to engage the threaded portion C of the holder, so that the bar E may be screwed on to the portion C of the body and make good electrical contact therewith. By screwing the portion E on to the portion C the plunger D in the axial hole G is forced transversely across the transverse hole to retain the electrode H securely in position. The body portion A and the cable-gripping device J, K of the holder are covered with an insulating sleeve L, so that the device can be safely held in the hand of the operator.—*October 12th*, 1933.

Nº 399,584

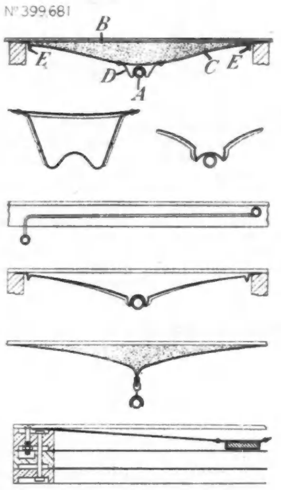


LIGHTING AND HEATING.

399,681. December 19th, 1932.—HEATING OR COOLING PANELS W. Deriaz, 16, Rue de Villereuse, Geneva (Switzerland).

The object of this invention is to enable a network of heating or cooling pipes spaced at considerable intervals to transmit to the radiation surface, such as wall panels, or the floor, a uniform intensity of heat or cold. The heating pipe is shown at A and the floor at B. The pipe is connected with a "distributor" C, which is made of iron or aluminium, by clips D. It has expansion folds at E, E. The space between the distributor and the floor may be simply filled with air or with "a material with a weaker conductivity than iron or aluminium." The thickness of the space between the distributor and the floor diminishes from the point nearest the pipe to the extremities of the distributor, so that the heat liberated near the pipe will have greater difficulty in reaching the floor than that liberated near the extremities of the distributor. The cross section of this latter, as also the thickness of the space, are so chosen that a determined, practically constant quantity of heat is transmitted to the floor per surface unit, and that the quantity of heat continuing its course in the distributor is sufficient in order that, at the extremity of this latter, the heat transmitted directly to the floor is equal to that quantity. In practice, the distributor has a constant thickness and is made in stamped aluminium or iron sheeting.—*October 12th*, 1933.

Nº 399,681

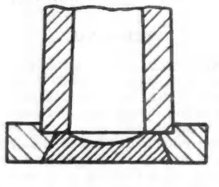


METALLURGY.

400,010. September 16th, 1932. INGOT MOULDS, J. Puppe, 19, Beethovenstrasse, Düsseldorf, Germany.

When an ingot is rolled down into a bar the exterior is naturally extended more rapidly than the centre, with the result that the bar or billet has hollow ends that must be cropped off. The inventor proposes to overcome this waste by making the ingots with rounded ends. The arrangement of the mould is shown in the illustration, from which it will be seen there is a false bottom that may be changed to give a contour of the end of the ingot appropriate to the subsequent rolling operations.—*October 9th*, 1933.

Nº 400,010

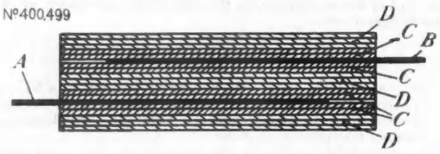


MISCELLANEOUS.

400,499. March 14th, 1933.—DI-ELECTRIC OF CONDENSERS, *William Warren Triggs, of Marks and Clerk, of 57 and 58, Lincoln's Inn-fields, London, W.C.2.*

The impregnation applied to the dielectric of electric condensers in accordance with this invention is said to have a very high degree of resistance to the initiation of glow discharges. Impregnated cellulose paper is placed nearest to the metal layers and at a greater distance from the metal layers impregnated rag paper is arranged. The reason for the improved performance lies in the greater chemical inactivity of the cellulose paper against the action of electrical glow and radiation processes, and also in the smaller di-electric losses of the rag paper, more particularly at the raised temperatures due to the di-electric heating. Examples of cellulose papers are those made from the fibres of soda cellulose and sulphite cellulose. The rag papers employed include those made from rags or from fibres of hemp or flax, that is, those whose fibrous materials are obtained from non-lignified constituents of plants. A and B are two metal foils, C is impregnated cellulose paper, and D is impregnated rag paper.—*October 26th*, 1933.

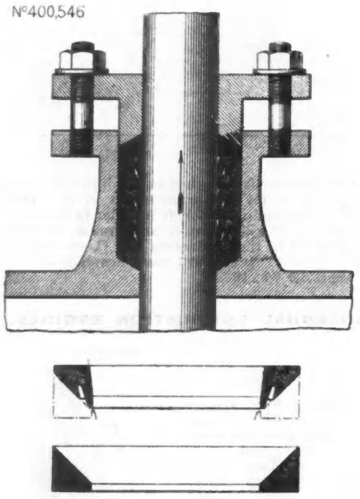
Nº 400,499



400,546. May 18th, 1933.—STUFFING-BOXES, E. R. Roy, Corner of Bridgewater and Wharton-avenue (Finderne). Bound Brook, New Jersey.

The object of this invention is to provide a packing which will grip the shaft or plunger only when leakage occurs. To this end a flexible lip is pressed against the shaft or plunger by fluid pressure when leakage occurs and the shaft moves in one direction, the flexible lip being released on the return stroke of the shaft or plunger. The packing therefore does not depend on the tightness of the gland to compress the packing to prevent leakage. The illustrations show the assembly of the packing rings in the stuffing-box and details of two of the rings, which are made of plies of cloth cemented together.—*October 26th*, 1933.

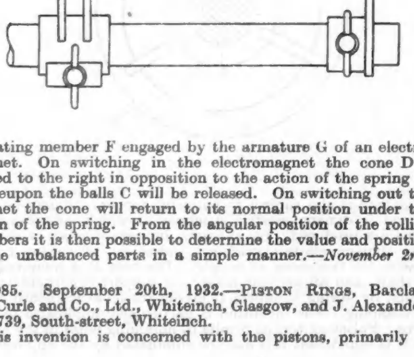
Nº 400,546



400,880. June 9th, 1933.—MACHINES FOR BALANCING ROTATING ELEMENTS, *The British Thomson-Houston Company, Ltd., Crown House, Aldwych, London, W.C.2.*

On the end of the shaft A of the body to be balanced is mounted the balancing head B, which is constructed as a hollow cylinder, and is provided with a track for the movable balance weights which consist of balls C. The cone D of a friction coupling normally holds the balls C in the track under the action of a spring E. The coupling cone is provided with a central operating member F engaged by the armature G of an electromagnet. On switching in the electromagnet the cone D is moved to the right in opposition to the action of the spring E, whereupon the balls C will be released. On switching out the magnet the cone will return to its normal position under the action of the spring. From the angular position of the rolling members it is then possible to determine the value and position of the unbalanced parts in a simple manner.—*November 2nd*, 1933.

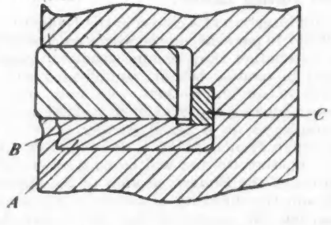
Nº 400,880



401,085. September 20th, 1932.—PISTON RINGS, Barclay, Curle and Co., Ltd., Whiteinch, Glasgow, and J. Alexander, 739, South-street, Whiteinch.

This invention is concerned with the pistons, primarily of oil engines, made of steel, but equipped with rings of cast iron. It is desired that the rings should have a rubbing surface in their grooves, also of cast iron. This surface is provided by the ring A, which is held in place by knurling at B and welding at C. In this way the welding is kept away from the cylinder walls, and will not produce scoring if it should break away.—*November 9th*, 1933.

Nº 401,085



Forthcoming Engagements.

Secretaries of Institutions, Societies, &c., desirous of having notices of meetings inserted in this column, are requested to note that, in order to make sure of its insertion, the necessary information should reach this office on, or before, the morning of the Monday of the week preceding the meetings. In all cases the TIME *and* PLACE *at which the meeting is to be held should be clearly stated.*

A Seven-Day Journal

The French Railway Disaster.

There is no parallel in French railway history to the lamentable accident that occurred on Saturday night last near Lagny, on the Est line, when the express from Paris to Nancy was telescoped by a train from Paris to Strasburg. Owing to a fog which was dense around Paris and made visibility very bad along the line the trains started at their regular intervals an hour and a half late. The express was composed of nine wooden coaches, and the Strasburg *rapide* was drawn by a " Mountain " type locomotive with steel coaches, the former train carrying a particularly heavy Christmastide load of passengers. Between Lagny and Vaires, about 16 miles from Paris, the express was stopped by signals for quite a long time, and the Strasburg train coming up behind at a speed of about 60 miles an hour, which was below the maximum speed permissible on that section of the line, practically ran through four coaches, smashing them up completely and destroying a fifth coach. At the time of writing the exact number of casualties is not known, but it is certain that over 200 passengers were killed and about 400 injured. The driver of the Strasburg train has been working on the line for more than twenty years. He affirms that the signal showed the section of the line to be at clear, and that he only saw the rear lights of the Nancy train when about 50 yards away. The signals are automatic throughout, and the driver's statement that the signal was at clear when he passed it appeared to be strengthened by the declaration of two witnesses that the detonator beyond the signal exploded under the two last coaches. A statement to the effect that the driver of a train on the up line stopped within 150 yards of the wreckage because he found that the signal went to danger while he was passing it, is repeated here merely as indicating suspicion that the automatic signals were not working normally. The driver and fireman of the Strasburg train were arrested, but later were released. This deplorable disaster is remarkable for the complete destruction of the wooden coaches, while the steel coaches of the Strasburg train appear to have suffered little damage. No one was seriously injured in that train. The Minister of Public Works has already declared that he will endeavour to obtain credits for the immediate construction of more steel coaches. The first stage of the technical inquiry, which has already been opened, is to determine the reliability of the automatic signalling system, particularly with regard to its instantaneous action. Simultaneously with the "raising" of the signal, a detonator is placed on the rail. If, therefore, the system were working properly, it is incredible that the driver of the Strasburg train should have failed to hear the particularly strident alarm whistle which is sounded on the locomotive by a signal at danger, or the detonator when passing a distant signal at danger. Pending the technical inquiry, public faith in the automatic signalling system in France has been shaken, and confidence will only be restored when it is definitely shown that the system is not at fault, or that adequate precautions have been taken to avoid disasters in the future. Our fullest sympathy is extended to the Compagnie de l'Est and to the friends of those who lost their lives in this disaster.

New Industrial Developments at Derby.

Considerable satisfaction is felt in the Derby district at the announcement that important extensions are to be made early next year to the works of Ley's Malleable Castings Company, Ltd., and Qualcast, Ltd., which firms have recently been devoting attention to the production of motor car parts. The new Ley's works, which will be completed in June, are to be built on three acres of land purchased from the London, Midland and Scottish Railway Company, and will, it is expected, give employment to about 400 men. The Qualcast works are to be extended by a new shop, which will give a 25 per cent. increased output for the firm. Extensions are also to be made to the works of Derby Cables, Ltd. A new air service which is being planned by the London, Scottish and Provincial Airways, Ltd., for a through service from Croydon to Renfrew, with halts at Derby and Manchester, is, it is understood, being supported by Rolls-Royce, Ltd., of Derby. The machines which will probably be used will be the Airspeed Courier with Armstrong-Siddeley 240 B.H.P. air-cooled engine having a cruising-speed of 140 m.p.h. The provisional schedule provides for four services per day in either direction, beginning in March with, at first, Manchester as a terminus.

The Late Sir Frank Baines.

Although Sir Frank Baines, whose death, at the age of fifty-six years, occurred on Christmas Eve, was an architect by profession, so much of his work was of a truly engineering character that it is fitting that his death should be recorded in these pages. He was a man of outstanding personality and great strength of purpose. For some years during his tenure of the office of Director of Works to the Office of Works he was responsible for the maintenance and restoration of many famous ancient buildings, of which Westminster Hall and the Banquetting Hall at Hampton Court are perhaps the most celebrated. In both cases the ancient woodwork had been riddled by the death-watch beetle until it was in a precarious condition. In Westminster Hall he effected restoration by introducing skilfully concealed steel work amongst the ancient timbers of the hammer beam roof, his effort being to preserve as much of the old wood as possible. His procedure has been, and still is, severely criticised by architects, some of whom believe that the beetle has not been got rid of by the poison used for that purpose, whilst others fear that stresses on the ancient walls have been set up by the new steelwork. In 1927 he retired from the Office of Works to take up private practice, and he was the architect to the two buildings at Millbank which have entirely altered its appearance—the house of Imperial Chemical Industries, Ltd., and Thames House. Sir Frank was an effective speaker and lecturer, and in November, 1922, delivered a lecture to the Institution of Mechanical Engineers on the subject of Westminster Hall. He was a firm believer in the restoration of ancient buildings to their old appearance, as far as possible, and a stout opponent of what he called, derisively, the " ivy tod " ruins. He was one of those men who give one the feeling that they would succeed in whatever they undertook.

Rural Water Supplies.

On Thursday, December 21st, Sir Hilton Young, the Minister of Health, received a deputation from the Parliamentary Agricultural Committee on the subject of rural water supplies. The deputation pointed out that the Committee was anxious to learn on what conditions and through what channels the proposed Government grant of £1,000,000 would be made. It regarded the importance of the complementary problem of sewage disposal, and emphasised the need of a comprehensive plan of water supplies as a whole. In his reply, the Minister stated that he would consider the various points raised by the deputation and would be glad to keep in touch with the Agricultural Committee. The scheme was intended to assist rural supplies, and its object would be the development of local resources. At the same time, whenever the technical circumstances demanded a scheme on a wider basis, full use would be made of the Regional Committee machinery. Speaking in the House of Commons on Thursday evening, December 22nd, in reply to a question put by Mr. Alan Chorlton, asking whether the organisation of the Ordnance Survey could be used for the purpose of a hydrogeological computation of our water resources, the Minister stated that he was informed that the Ordnance Survey was not equipped for work of that kind, but that the Government derived most important and useful information from the Geological Board.

A Temporary Grid Failure.

A temporary failure, caused by flashing over of the insulators on the national grid in the Southern Counties, occurred during the night of Tuesday, December, 19th, and on the following morning, when serious delays were caused to trains running between London and Brighton and other Sussex towns. In many cases a delay of over three-quarters of an hour took place, owing to lack of lights for signalling and of power for traction purposes. The failure was directly caused by the spell of fog and frost, which was of unexpected severity, and a repetition of similar troubles will in future be guarded against by increasing the number of insulators from eight or nine to ten or eleven as may be required. Similar trouble has been experienced in Scotland and the North, but was quite unexpected in the affected area. Owing to the unexampled call for current the three stations—Brighton, Three Bridges, and Croydon—were seriously overloaded in turn, and it is some satisfaction to know that the safety and protective gear worked in every case without a hitch.

Co-operative Profit Sharing.

Trading results for 1932 in co-operative prcductive societies were published recently by the Co-operative Productive Federation, the details serving to stress the difficult conditions with which that year had to contend. The forty-three federated societies had an aggregate membership of 15,854, with a share and loan capital of nearly 1½ million sterling. There were 7497 employees at the end of the year, the wages bill totalling just over three-quarters of a million pounds. The turnover came to 2½ millions, and gave a net surplus of £106,856; both these latter totals show a slight decrease over those for 1931. From the surplus, capital received £6277, about £29,948, and customers £54,150, while grants to educational and charitable purposes amounted to £3891. There are five societies in the group devoted to metal-working and miscellaneous industries, four of which are connected with the engineering and allied trades. The largest of the four is the Walsall Locks and Cart Gear, Ltd. At the end of 1932 it had 326 members, a share and loan capital of £22,839, and 307 employees, a turnover of £61,476, giving a net surplus of £852, of which £21, or 1½ per cent., was distributed to capital, and £483, or 4d. in the £ on wages, to labour. Of the other three engineering societies, Chesham Builders, Ltd., was the only one declaring any bonus. It had 48 members, and with a capital of £839 and 26 employees, it did business to the value of £9777, and had a surplus of £239. Sixpence in the £ on wages was given to labour, the distribution totalling £73. Alcester Needlemakers, Ltd., had 139 members and a capital of £3306. Its turnover amounted to £13,471, although only seven workpeople were employed at the end of the year. There was a net surplus of £21. The last of the four societies in this group is the Leicester Carriage Builders, Ltd. With a membership of 182 and a share and loan capital of £6281, its business amounted to £12,085, resulting in a net loss of £413. It had 27 workpeople on its pay roll. The figures here given complete the results of profit-sharing for the year 1932, the details for ordinary competitive concerns, summarised from the Ministry of Labour's return, having been given in a Journal note on June 23rd last.

Shipbuilding Outlook on the Clyde.

The river Clyde is at the moment the busiest shipbuilding centre in the world, for in the last quarter of the year shipbuilding orders aggregating more than one million pounds were placed with shipbuilding yards and engine works on the river. Added to these new orders, there are good prospects of an early resumption of work on the new Cunarder, while important Admiralty contracts are expected. New British and Colonial orders will, it is anticipated, be placed early next year, and it is understood that tenders have been recently submitted by Clyde firms for the reconstruction of the Brazilian and the Estonian Navies. Although the output of the Clydeside shipyards during 1933 was the lowest on record, only thirty-one ships of about 56,000 gross tons total being launched, that total was greater than the total output of English yards. The industrial future must still be viewed with restrained optimism, and it is still worthy of record that, whereas at the beginning of 1933 only roughly 5 per cent. of the shipyard berths were occupied, the number now in use, which, it is hoped, will shortly be considerably increased, is about 25 per cent. of the available shipbuilding berths on the river.

The Science Museum.

An extension to the Children's Gallery of the Science Museum, South Kensington, which was officially opened on Friday, December 22nd, further extends the idea worked out by Sir Henry Lyons, and begun two years ago. The gallery as a whole has now been rearranged and an endeavour has been made to bring the old exhibits and the new into a more logical sequence. The first exhibit in the gallery is the practical demonstration of a rainbow, and as far as possible the physical exhibits have been arranged near the entrance, the visitor passing from them to practical applications. They include the existing large interiors representing the work of the smith, the flint worker, and the potter, along with the working models illustrating the production of power by the energy of animals, by wind, water, and steam. These are followed by small interiors depicting the development of lighting through the ages, and a series of new scale models illustrating the benefits which have been conferred upon the community by the advent of gas and electric power. Some additions have also been made to the exhibits of lifting appliances, all of which can be worked by the visitors themselves. The progress in methods of communication is well illustrated by a series of exhibits, the first of which shows a primitive beacon and the last a modern telephone exchange. A number of exhibits from the exhibition of photo-electric cells held during last summer have now been transferred to the Children's Gallery, and arrangements have been made to exhibit several short films. The educational value of the old and new exhibits will doubtless be greatly appreciated during the school holidays.

New Shipbuilding Orders.

During the past week several important shipbuilding orders have been placed. It is announced by the Peninsular and Oriental Steam Navigation Company, Ltd., that an order has been placed with Vickers-Armstrong, Ltd., of Barrow-in-Furness, for the construction of a fast mail and passenger liner of over 20,000 gross tons for the P. and O. fleet. The new ship, which will give employment to between 3000 and 3500 workers for a year and a-half, will, we understand, be propelled by twin-screw geared turbine machinery taking steam from water-tube boilers. John Brown and Co., Ltd., of Clydebank, are to build a twin-screw motor cargo liner for the Australian and New Zealand service of the Commonwealth and Dominion Line. It will have a tonnage of about 8800. On the other side of the Clyde, at Renfrew, Lobnitz and Co., Ltd., are to build a large gold dredger for working in the alluvial valleys of the river Pek on the Yugoslav-Roumanian border. It will be designed to dig and treat 6000 tons of alluvial gravel per day and will float in a pond or paddock, rejecting the treated material astern and excavating forward, thus creating the pond in which it works.

Recent American Express Locomotives.

By E. C. POULTNEY.

No. II.

(Concluded from page 617, December 22nd.)

4–8–2 and 4–8–4 Type Locomotives.

In considering now engines of the eight-coupled type, the first example given in Table II. (repeated from last week) represents the latest "Mountain" type, introduced by the Pennsylvania in 1930. Actually the design is a development of an experimental 4–8–2 built for test purposes at Altoona in 1923. It may be interesting to note briefly the evolution of this type of engine on the Pennsylvania. Prior to the building of the 4–8–2 type, all important trains were handled by the "K.4.s. Pacifics" or the "E.6.s. Atlantics," but heavier trains and the difficult road between Altoona and Pittsburg, between which points the line crosses the Alleghenies, demanded engines of much greater power. Accordingly a large 4–8–2 was designed in 1923. This engine, with 37in. by 30in. cylinders, 72in. wheels, and 250 lb. boiler pressure, represented a great advance in power over the existing engines mentioned, as it had a rated tractive effort of 64,550 lb. The boiler had a type E superheater and a total heating surface of 6704 square feet with a grate area of 70 square feet, and weighed, engine only, 384,300 lb. A number of trials were made with this engine, both on the plant and on the road, and experience showed that at high powers the steam volume given by the boiler was deficient. Alterations in the boiler diameter were made, and with good results, and a revised design of generally the same dimensions appeared in 1926. This engine, one of which is illustrated in Fig. 9, is, like the original, classified M.1. The boiler is remarkable for the very large fire-box and combustion chamber, the latter being 8ft. 2in. long, and in consequence the tube length is only 19ft., which is short for an eight-coupled engine. This arrangement was used also for the trial engine. The cylinders, wheels, and steam pressure are as before, but instead of being hand fired a stoker is fitted. During 1926 and 1927 the Pennsylvania placed 200 of these locomotives in fast passenger and freight traffic. They were built by Baldwin and the Lima Locomotive Works. Their success led to the design being developed further, and in 1930 those of the class M.1.a., as next shown—Fig. 10—were built. The dimensions given in Table II. relate to the M.1.a. class, but are applicable to the previous M.1., except for the weights and data relative to the tenders which are much longer for the newer locomotives. In construction, the M.1.a. class differ in having a one-piece cylinder casting in steel, with a saddle, which, as in the case of the "K.5 Pacifics," is long enough to constitute practically the bottom of the smoke-box. A further change of importance is the inclusion of a feed-water heater; the type used is the Worthington S pattern, of very large capacity, capable of supplying 62,108 lb. of water per hour. The tender is of exceptional size, with a 22,000-gallon tank and space for 63,000 lb. of coal. A scoop is provided.

Table II.—*Examples of Recent Passenger Locomotives of the 4–8–2 and 4–8–4 Types.—General Dimensions and Ratios.*

Fig. 10 (Below)—P.R. Class M.1.A. 4-8-2 Type Locomotive, 1930

As was the case with the two previous designs, one of these engines has been tested on the Altoona plant and shown a very high capacity. When working all out the indicated horse-power developed was 4662 and at the draw-bar 4034. This power output was attained at 240 r.p.m. and 65 per cent. cut-off. The boiler showed an equivalent evaporation of 113,368 lb. per hour, or an actual of 92,084 lb. The dry coal fired per hour was 21,271 lb. and the steam pressure maintained averaged 241 lb. per square inch delivered at a total temperature of 733 deg. Fah.

The Baltimore and Ohio (B. and O.) engine—Fig. 11—has been built by Baldwin to the requirements of Mr. Emerson. The design is experimental, being specially worked out to comply with severe weight and clearance limitations, whilst, at the same time, developing high power for operation in heavy passenger services. It will be noted that the engine is very light in comparison with the heating surface provided. The cylinders are 27½in. by 30in., and the piston valves have a diameter of 12in. and a full gear travel of 7in. when the cut-off is 87 per cent. As will be seen, Walschaerts gear is used. The superheater is of the E type, and two Nicholson syphons are fitted in the fire-box. Other equipment includes cast steel cylinders, Sellars exhaust steam injector, power reverse gear, and a mechanical stoker of the Lower pattern. The length between the tube plates is 21ft., and there are fifty-nine 2¼in. tubes, and 224 3½in. flues. The superheating surface is 2451 square feet, or 30·8 per cent. of the combined total of 7957 square feet. All the motion parts have been carefully proportioned to save weight, and the same remark applies to the frame construction, which is of the normal type, but the cross stretchers are welded to the side members, thus eliminating to a large extent bolts in the building of the frame structure. The tender is of the Vanderbilt design, and runs on two four-wheeled trucks. It carries 18,000 gallons of water and 20 tons of coal, and has a loaded weight of 273,000 lb., and is light for the carrying capacity. A further engine of the same general design is also in traffic, but having an Emerson water-tube fire-box and type A superheater.

The dimensions of a large locomotive having the 4–8–4 wheel classification is given by the next example in the Table. Five were built in 1927 by the American Locomotive Company for the Delaware, Lackawanna and Western (D.L. and W.) for fast passenger service, principally between Hoboken, N.J., and Scranton, Pa. These engines are remarkable for the large size of their coupled wheels, and the high tractive effort of 64,500 lb. The 77in. drivers were, when the engines were built, the largest found in an eight-coupled design. The line between Hoboken and Scranton crosses the Pocono Mountains over steep gradients, both east and west-bound, but on the more favourable sections of the run some high speeds are required; hence the large diameter driving wheels. These engines are stoker fired, and provision is made for the application of a booster to the rear axle of the trailing engine truck if required.

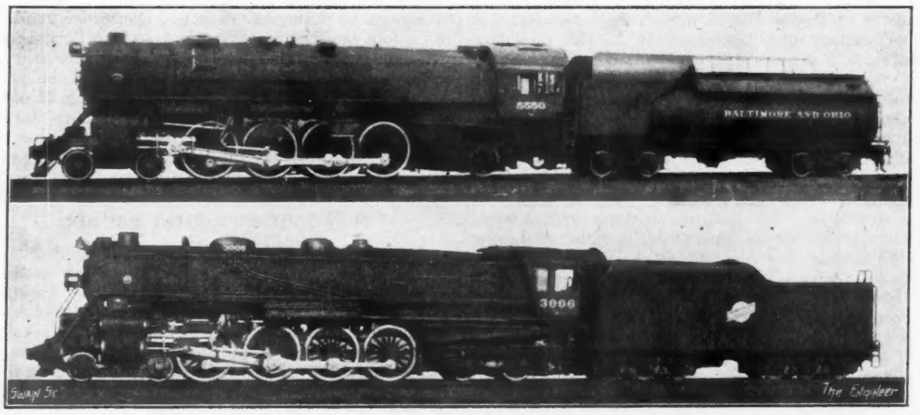

Fig. 11 (Above)—B. and O. 4-8-2 Type Locomotive

Fig. 12 (Below)—C. and N.W. 4-8-4 Type Locomotive

The Baldwin Locomotive Works built the Chicago and North-Western (C. and N.W.) engines represented by Fig. 12, which are amongst the largest passenger engines so far built. The tractive effort with the normal boiler pressure of 250 lb. per square inch is 65,200 lb., or, with the trailing truck booster, 76,500 lb., but if the pressure is raised to 275 lb. per square inch, for which provision is made, the tractive effort will be 71,800 lb. and 84,200 lb. respectively.

The locomotives are fitted with type E superheaters, Worthington S type feed heaters, three syphons, two in the fire-box and one in the combustion chamber, a modified B type stoker, and a tangential steam separator which is fitted to the steam pipe in the dome. The main throttle is of the multiple-valve pattern, housed in the superheater header. A notable feature is the one-piece cast steel underframe, which includes the cylinders and saddle, and the absence of outside steam pipes will be noted, their place being taken by cored passages in the saddle. The frame casting is 58ft. 3in. total length, and has a weight of 72,500 lb. The boiler has a largest diameter of 100in. outside, where the plates have a thickness of $1\frac{3}{16}$in. There are fifty-one 2in. tubes, and 214 3½in. flues, and over the tube sheets the length is 21ft. The 27in. by 32in. cylinders have 14in. piston valves, and five engines have Baker gear, and thirty Walschaerts. Power reversing gear is fitted. The main connecting-rods are of the Woodard or articulated design, a construction which relieves the main pins of part of the piston thrust, and dispenses with the usual knuckle-pin arrangement in the side rods. The main and intermediate journal boxes have brasses of the adjustable three-piece type, and the bearings are 13½in. by 14in. for the main, and 12in. by 14in. for the others. Of the thirty-five locomotives, twenty-five have tender trucks fitted with the American Steel Foundries roller bearing units, and all the tenders have cast steel water bottom underframes, as illustrated by Fig. 13. The tank capacity is 18,000 gallons, and the fuel space is sufficient for 20 tons of coal, and, when thus loaded, the tender weight is 320,000 lb. Referring to the feed heater, it may be mentioned that the hot-water pump of the reciprocating pattern is seen arranged over the right-hand cylinder valve casing. The heater itself is just in front of the chimney. The sloping of the front of the cab is becoming common practice, as it materially adds to accessibility for the examination of the fire-box stay bolts.

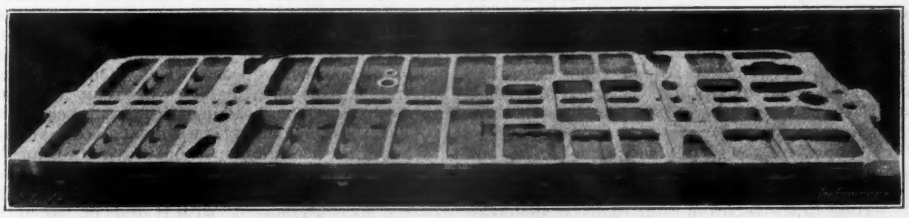

Fig. 13—Cast Steel Water Bottom Tender Frame, C.N.W. 4-8-4

As already pointed out, these locomotives are amongst the largest so far built for passenger service, and a few of the more important dimensions which will give an idea of their size are given as under :—

Height to top of chimney from rail	15ft. $11^3/_{32}$in.
Height from rail to boiler centre	10ft. 8in.
Driving axle wheel base	20ft. 6in.
Rigid wheel base	13ft. 4in.
Wheel base, engine	48ft. 7in.
,, ,, locomotive	91ft. 1in.
Total length over couplers	103ft. 4in.

Early in 1930 the Baldwin Locomotive Works delivered fourteen large 4–8–4 engines to the Great Northern (G.N.) for operating passenger trains on the more level sections of the line, and one is illustrated by Fig. 14. These locomotives, the leading dimensions of which are given in Table II., are remarkable for the large size of the coupled wheels, which have a diameter of 80in., the largest applied to an eight-coupled design. The boiler is of nickel steel, and has a large fire-box with combustion chamber, a type E superheater, and is fed by an exhaust steam injector. There are 195 3½in. flues, and thirty-eight 2¼in. tubes, and the length over the tube sheets is 22ft. The frames are of the normal cast steel bar type, and the cylinders are also of cast steel. Walschaerts' motion imparts a 7½in. full gear travel to the 14in. piston valves, and a power reverse gear is fitted. The working steam pressure is 225 lb. per square inch, and four valves are used; they are loaded to blow off at 225 lb., 226 lb., 227 lb., and 228 lb. respectively. The two 8½in. cross-compound air compressors for the brake are mounted on the smoke-box front and use superheated steam. A multiple-valve throttle is fitted. The leading truck has outside journal boxes, and is of a special design developed by the builders, having a one-piece framing of cast steel; the two side frames are connected to each other front and back, thus enclosing the wheels, and these end sections are braced to the centre by longitudinal stiffing members. The spring gear is equalised and the centering rockers are of the constant-resistance type. The leading truck wheels are 36in., and those of the trailing trucks of equal size are 45in. diameter. A tender of the Vanderbilt design is used, the body of which is welded throughout. It is mounted on a Commonwealth cast steel frame of the water bottom design. The six-wheeled trucks have cast steel frames. These locomotives use oil fuel, and there is tank capacity for 5800 gallons of oil and 17,000 gallons of water.

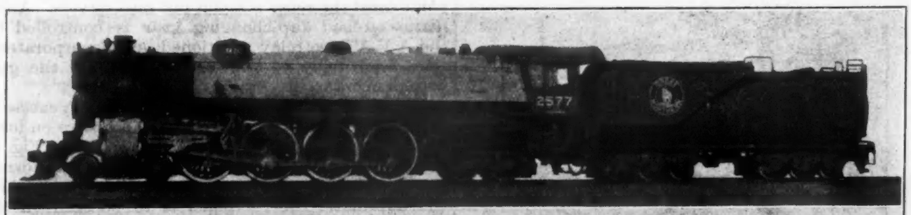

Fig. 14 (Above)—G.N. 4-8-4 Type Locomotive

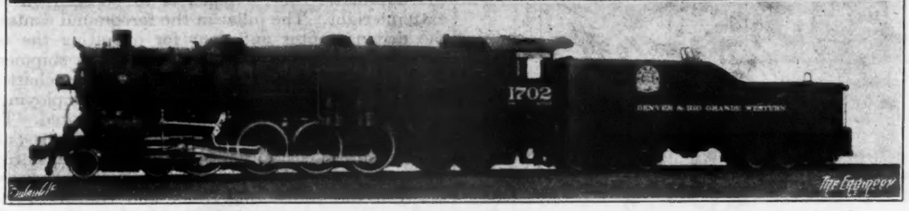

Fig. 15 (Below)—D. and R.G.W. 4-8-4 Type Locomotive

For working heavy passenger traffic over a very difficult road, the Denver and Rio Grande Western (D. and R.G.W.) utilise the class of engine shown by Fig. 15, built to the dimensions given in the table by the Baldwin Works. These engines are equipped with feed-water heaters, type E superheaters, Nicholson thermal syphons, power reversing gear, and cast steel cylinders. The valves, of the piston type, have a diameter of 14in., and are operated by Walschaerts motion, modified to provide variable lead which is increased as the gear is linked up. The arrangement is interesting, and is as follows. The upper end of the combining lever is slotted out to receive a die block fitted with a pin, which also passes through the forked end of the radius rod, which connects with the die in the expansion link. The pin engaging the radius link at the combining lever end is also long enough to engage with a short lifting link connecting with the horizontal arm of a bell-crank lever, the vertical member of which is, in turn, connected by a rod with an arm on the main reversing shaft. When the motion is in the mid-gear position, the arm on the reversing shaft, which is at 180 deg. with the lever operating the lifting links for the radius rod, has pushed the vertical member of the bell crank over slightly, and so raised the die block in the slotted end of the combining link, thus increasing the distance between the radius rod pin and the valve spindle centre, thereby adding to the lap and lead movement. The lead is, therefore, increased, but as the lever on the reversing shaft is opposite that controlling the lifting links, it follows that when the motion is put over into or towards either full forward or full back gear, the upper arm of the bell crank is depressed and the die in the combining lever, therefore, brought nearer to the valve spindle centre, thus reducing the lead opening. The bell crank and its connection with the die in the combination lever can just be made out in the illustration of the engine. The lead is zero in full gear, and increases to ⅜in. at 25 per cent. cut-off.

The boiler is of the usual round-top, radial-stayed description. It carries a pressure of 240 lb. per square inch, and has a fire-box fitted with a combustion chamber, and the grate has an area of 88 square feet. A mechanical stoker is provided. There are 195 3½in. flues, and forty-three 2¼in. tubes, and the length over the tube sheets is 22ft. The main journal bearings are 13in. by 14¾in., and those for the other coupled axles are 11½in. by 14¾in. For the leading truck the wheels are 36in. diameter, with journals 7in. by 14in., and for the four-wheeled trailer the wheels are 42in. with journals 9in. by 16in. Two 8½in. cross-compound compressors are fitted, and the air brake acts on all the coupled and the tender wheels. The tender, which runs on six wheels, carries 29 tons of coal, and has tank capacity for 14,000 gallons of water. The wheels are 36in. diameter, and the journals measure 6in. by 11in. These engines operate over the main line extending from Denver, Col., to Ogden, Utah, a distance of 782 miles, traversing the Rocky Mountain district, and crossing the Continental Divide at Tennessee Pass, 280 miles from Denver, at an elevation of 10,239ft. From the east the gradients are 1·42 per cent., and from the west the maximum gradient is 3 per cent. The track is laid with 100 lb. and 110 lb. rails.

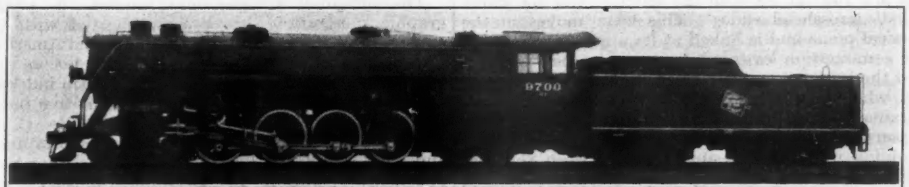

Fig. 16 (Above)—C. M. St. P. and P. 4-8-4 Type Locomotive

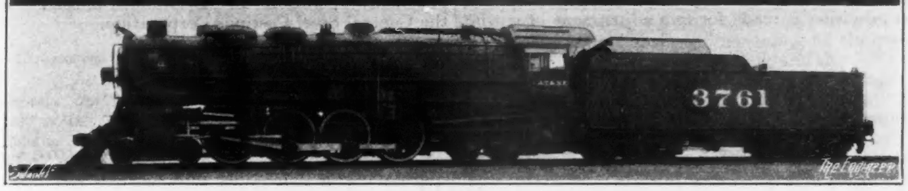

Fig. 17 (Below)—A.T. and Santa Fe 4-8-4 Type Locomotive

The next example of the 4–8–4 type is one for the Chicago, Milwaukee, St. Paul and Pacific (C.M. and St. P.), built by Baldwin in 1930—Fig. 16. The engine, in many respects, is similar to the "Pacifics," the main dimensions of which are given in Table I., and certain details, where practicable, are interchangeable. The engine has roller bearings for the front and hind trucks, and is replete with a feed-water heater, E type superheater, three Nicholson syphons, and stoker. The unit cast steel framing has the cylinders cast integral, and the "Pacifics" have the same type of frame construction. Laird type crossheads are common to both designs, and the valve gear is the same type, and arranged in the same manner. The boiler is of considerable size, and is fitted with a combustion chamber in conjunction with a fire-box of ample proportions, having the large grate area of 103 square feet. There are 218 flues, 3½in. diameter, and fifty-six 2¼in. tubes, and over the tube plates the length is 21ft. The boiler demand factor of 567 indicates considerable steaming power, relative to the horse-power capacity of the cylinders. The piston valves are 14in. in diameter. The tender carries 20 tons of coal and 15,000 gallons of water, and has roller bearings for the axles.

Both the C.M. and St. P. "Pacific" and "Modified Mountain" type locomotives are fitted with the Coffin feed-water heater, and the same is used also for the later "Hudson" type 4–6–4 engines of the N.Y.C. A short description of this heater will be of interest. The Coffin heater is of the closed type, and consists essentially of the heater and the feed pump units, both separate. The heater is semi-circular in shape, its radius being made to conform to the individual smoke-box to which it is applied. It is usually built into the upper part of the smoke-box, just ahead of the chimney, or it may be mounted outside at the front; but, owing to its shape, it is flush with the top of the box in either case. The semi-circular form allows of the tubes being fixed in rigid tube sheets as their curved shape naturally allows for expansion. The tubes are of copper. The water takes five passes through the heater, the first being farthest from the steam inlet, and the last directly next to the steam baffle. An auxiliary open heater is fitted in the tender. Its function is to combine the condensate with the feed water, and liberate dissolved oxygen. The pump is of the centrifugal pattern, turbine-driven by direct-coupling. It is placed below the tank level and usually mounted at the hind end of the engine under the footplate at one side where it is accessible for attention.

The Atchison, Topeka and Santa Fé (A.T. and S.F.) locomotive illustrated by Fig. 17 is probably the largest of its type for passenger service. The engine frame construction differs from that employed for any of the other engines described, in that the cylinders and valve chests are cast in one piece together with the saddle, and bolted and keyed to a one-piece cast steel bed frame. The cylinders are also of cast steel and special care has been taken with the form of the exhaust passages which are cored in the cylinder casting. It is claimed that, compared with cast iron, the use of cast steel for cylinders saves 25 per cent. in weight. All the coupled axles are hollow bored and so are the main crank pins. The big ends have floating bushings and the crossheads are of the Laird pattern. All the revolving and 50 per cent. of the reciprocating weights are balanced. The writer believes that this proportion of balance for reciprocating parts is usual American practice. The piston valves actuated by Walschaerts motion have a diameter of 15in. and the long full gear travel of 9in. when the cut-off is 85 per cent. The long valve travel is responsible for the inclusion in the valve gear of a novel means for overcoming unfavourable angles in the motion parts. This device, which magnifies the motion imparted to the valve for a given swing of the expansion link, consists of a short lever rocking about a fulcrum fixed in the outer end of the valve spindle crosshead slides. This lever moves in the vertical plane and is linked at its upper extremity to the combination lever, while at a point between this and the fulcrum, connection is made with the radius rod, which has the effect of increasing the valve travel obtainable for any given position of the die in the expansion link, thus maintaining a normal swing and avoiding unfavourable angularity between the link and the excentric rod. A power reverse gear is applied and provision is made for fine adjustment of cut-off by fitting a reverse gear quadrant with more teeth than usual. The boiler is of the radial stayed type and has a type E superheater, with header fitted with a multiple valve throttle valve. The blast pipe is very low in the smoke-box, and has a ported nozzle of the Layden type, designed for a large-diameter chimney. The tubes are fifty-seven in number and of 2¼in. diameter, and there are 231 3½in. flues. The length over the tube sheets is 21ft. The tender carries 20 tons of fuel and 15,000 gallons of water, the weight loaded being 292,260 lb. There are twelve wheels, having a diameter of 33in., and the axle journals are 6in. by 11in. The air brake acts on the coupled wheels of the engine and also on the tender wheels. These locomotives operate between La Juanita, Col., and Winslow, Arizona, 636½ miles, and between the latter point and Clovis, N.M., 503·5 miles, the last section being a mountain division. The mean speeds vary from 35 to 39 m.p.h. The trains are made up of nine to sixteen cars, equal to 793 and 1120 tons, and the engines make these division runs unchanged.

Referring to the tables of dimensions, it should be pointed out that the heating surfaces of the fireboxes in all cases includes that contributed by the combustion chamber and also, where fitted, the syphons and the fire-brick arch tubes. Weight, when given in tons, refers to tons of 2000 lb., and water capacities are all given in U.S. gallons.

Conclusion.

In presenting this review of recent design of express passenger locomotives as used in the United States no attempt has been made to go far into the details of construction, it being the writer's aim to give a general survey of the modern tendencies of design and to mention some notes on the fittings now included in American practice.

The information given and the various photographic illustrations have been collected with the assistance of the various builders, viz., the American Locomotive Company and the Baldwin Locomotive Works, and, in addition, the writer is much indebted to Mr. P. W. Kiefer, chief engineer of motive power and rolling stock, New York Central; Mr. G. H. Emerson, superintendent of motive power, Baltimore and Ohio; and Mr. F. W. Hankins, assistant vice-president, operation, Pennsylvania Railroad; and the General Steel Castings Corporation.

A.C. Voltage Regulators.

No. VI.

(Concluded from page 614, *December 22nd.)*

TWO types of induction regulator are made by the Metropolitan-Vickers Electrical Company. One is for capacities up to 100 kVA and for pressures ranging from the lowest to 3500 volts. The other for capacities in excess of 100 kVA and for voltages up to 15,000. Single-phase, polyphase, and twin regulators for overcoming phase shift are supplied for hand, remote and fully automatic control, according to requirements. Small polyphase regulators are generally employed under conditions which do not demand the elimination of phase shift, such as on a dead-ended feeder, but the Metropolitan-Vickers Electrical Company is prepared to supply twin regulators of low capacity if called for. Some of this company's induction regulators were described in our issue of April 16th, 1926. Since then certain modifications have apparently been made, notably in connection with automatic control. The latest relay for that purpose has two sets of contacts, one of which makes a circuit by a decrease of voltage. The other performs the same operation when the voltage increases. The opening and closing of the contacts controls the operation of two contactors, which determine the direction of rotation of the motor which controls the induction regulator-operating mechanism. It may also be made to control on-load tap-changing gear, the field regulator of a synchronous condenser, &c. As Fig. 62 shows, the coil A has a floating core B, attached to a beam pivoted at D, the weight of the core B being partially balanced by an adjusting spring E. At the end of the beam there are contacts F G. When the beam moves upwards, F touches H and when downwards G touches J. In circuit with the moving contacts is a small electro-magnet K, with poles L, which exert a pull on the armature N, thereby preventing chattering at the contacts. The movement of the core is damped by a dashpot O. By means of a spring connection between the dashpot plunger and the end of the pivoted beam, a quick break is ensured at the contacts. By the movement of the plunger the spring is compressed or extended, but owing to the pull of the magnet K the beam does not move until the spring, by overcoming the effect of K, causes the contacts to be snapped open.

When an induction regulator or tap changer is controlled by the beam relay the coil A of the latter is connected across the output terminals of the regulator. If the pressure does not exceed 500 volts it is connected directly, but if the circuit pressure is greater than that value it is connected to a fused potential transformer. A low tension supply is necessary to operate the regulator motor, and this may also necessitate the use of a transformer, although in some cases a local low-tension D.C. or A.C. supply may be used. A single operating transformer is never employed to supply both the motor and beam relay, as fluctuations, brought about by voltage drop due to the motor current in the windings of a small transformer, might affect the relay.

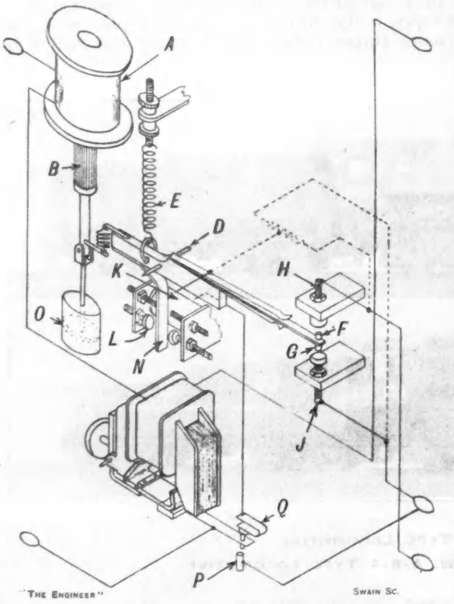

Fig. 62—Details of Balanced Beam Relay

A fall in voltage causes the core B to take up a lower position, with the result that a circuit is completed at H, and the associated controlling apparatus is put into action. Similarly a rise of voltage closes the contacts at G J. Relays of this kind are made in four types, designated A V, A V A, A W, A W A, and A V and A W differ electrically, the latter having a current winding on the control solenoid in addition to the voltage winding. This compounding of the regulator makes possible the introduction of a simple form of line drop compensation and introduces an equalising winding for use where several relays are working in parallel. The A V A and A W A relays have a no-volt element, to be seen below the relay. In the ordinary way, in the event of the supply voltage failing, the relay would close the circuit at H, and regulating mechanism might be moved to the maximum pressure position.

On the restoration of the supply, the system would therefore operate initially at maximum voltage, with possible serious consequences. But when the voltage fails the no-volt element closes a circuit at P and opens contacts Q thus bridging H, the result being that, provided the motor supply is still available, the voltage is reduced to the minimum value in readiness for the restoration of service. When the relay is energised contact P is normally open and contact Q closed. The latter is normally in series with H or J, but when the voltage fails this circuit is broken and contact P closes and causes the regulator to take up the position of minimum voltage. The circuit shown dotted is simply a centre-tapped resistance of high value connected across the relay contacts to minimise sparking when suddenly opening or closing the magnetic circuit of an additional time delay relay.

In the event of the relay shown being disconnected, owing, for instance, to the blowing of a fuse in the potential transformer or relay circuit, in the absence of the no-volt element there would be no control over the supply voltage, which might easily rise to a dangerous value with a fall in load. Under these conditions, however, the no-volt element would cause the voltage to be reduced to a low and safe value until the relay is again put into service. Automatic on-load tap-changing gear is controlled by the A V A type relay mentioned, and incorporates a time limit relay to prevent operation of the gear with momentary fluctuations of voltage.

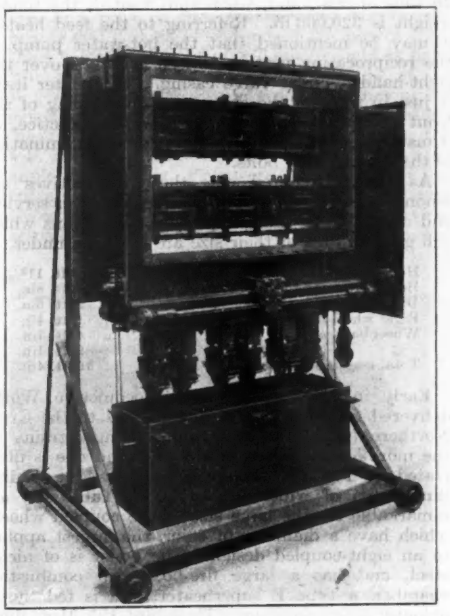

Fig. 63—On-Load Tap-Changing Equipment

For use on circuits working at voltages in excess of 33,000, or currents in excess of 100 ampères on-load, tap-changing equipment of the type shown in Fig. 63 is made. A 10,000-kVA, 33,000/6600 transformer fitted with this gear is shown in Fig. 64, in which the automatic control panel is to be seen on the extreme right. The pillar in the foreground contains the driving motor and gear for operating the tap changer, and it can easily be detached for shipment. A diagram of connections and sequence chart is shown in Fig. 65. The usual scheme of employing a reactor with a mid-point tapping is adopted. The selector " off load " switches are rotary switches, and are mounted either above the main transformer windings on insulators fitted to the dividing wall between the transformer tank and transfer switch tank, or in a pocket on the tank side above the transfer switch tank. Two of these switches are provided for each phase. The duplicate transfer switches and cam-operating mechanism are housed in a separate oil filled compartment.

Referring now to the diagram and sequence chart, Fig. 65, it will be perceived that the tapped portion of the transformer consists of sections T2 to T5, and the operating stages for the various tapping positions are indicated in the sequence chart. The transformer winding terminal 8 is connected successively to terminals T5 to T2 through the centre-tapped reactor. The number of voltages obtainable in this particular case is the same as the number of winding tappings, but if a large number of steps are necessary, the reactor can be made to double the number of effective tapping positions. Tapping position No. 1 gives the maximum voltage, and, as shown in the sequence chart, transfer switches X and Y are both closed, and the tap changers *x* and *y* are both in position 1.

Terminal 8 of the transformer winding is then connected to terminal 5 through the two short-circuited sections of the reactor. To reduce the voltage one step corresponding to position No. 2, transfer switch X is first opened, thus transferring all load to the circuit Y, tap changer *x* is moved to position II., and transfer switch X is closed. Transfer switch Y is then opened, thus transferring all load to the X circuit, tap changer *y* is moved to position II., and transfer switch Y is closed. Thus, the winding 8 is now connected to terminal T4, and, consequently, one tapping section is cut out. To reduce the voltage another step, corresponding to position 3, a similar process is followed during which the tap changers are moved from position II. to III. In all the main tapping positions both transfer switches are closed, and both tap changers are in the same position, so that the particular tapping in use is always connected to terminal 8 through the short-circuited halves of the reactor, and the reactive drop in these windings is eliminated. Each tapping change is brought about in a very short time by one revolution of the motor-driven mechanism.

0 Indicates "Switch Closed".

"THE ENGINEER"

FIG. 65—TAP-CHANGING CONNECTIONS

As is now well understood, during each half of the cycle the full load current is carried momentarily by one-half of the reactor winding, which, in the case of this tap-changing equipment, is designed to carry the full load continuously, so that if for any reason the tap-changing operation is not completed, it will not be overloaded. It will be equally evident that as at the end of the first half of the cycle the complete reactor is momentarily connected across two tappings, the line voltage is then raised by one-half of a step until the transfer switch Y is opened, when the voltage is increased by an amount corresponding to the full step. For lower outputs, *i.e.*, up to 100 ampères, another type of tap-changing gear is made, the circuit for which is given on page 85 of THE ENGINEER of July 26th, 1929, but the arrangement of the gear itself has now been altered. Mercury switch "on load" tap-changing gear is also supplied by the Metropolitan-Vickers Electrical Company for transformers up to 20 ampères and 11,000 volts.

ADJUSTABLE LINE DROP COMPENSATOR.

Reference was made in a previous article to line drop compensators, which enable the voltage of a feeder or transmission line to be regulated at the sending end of the line, so that the required voltage is maintained at the receiving end. It is necessary, in order to do this, for the regulating relay which controls the output voltage of the induction regulator or other arrangement to be connected in a circuit which accurately reproduces the receiving end conditions, as the regulation of the line will then be the same as if the controlling relay were at the terminal end. Various methods exist by which compensation may be made in the regulating relay circuit for the effects of impedance drop at different loads. The object of these compensating devices is to subtract vectorially from the voltage applied to the regulator (which is proportional to the sending voltage), a voltage equal to, but opposite in phase to the line impedance drop, the resultant voltage then representing accurately the conditions at the receiving end. To obtain a voltage representing the line impedance drop at different loads current transformers are connected in series with the load, and their output is fed to tapped resistances, the drop across which is subtracted from the voltage applied to the regulator coil by the voltage transformer.

By setting the resistances the voltage drop may be correctly adjusted, after which it will remain correct for all loads. As an alternative to this scheme, the output of the current transformers may be supplied to a current winding provided, in addition to the normal voltage relay winding, as incorporated in the Metropolitan-Vickers type A W relay, thus providing a number of ampère turns which are subtracted from those of the voltage winding, the operating flux being the resultant of the two. In order that the subtracted drop may be opposite in phase to the line impedance drop, provision is made for swinging it vectorially through a sufficient angle for adjustment by variation of the resistances, interconnection of the current transformers, or by similar methods.

Some of the commonly used compensating devices are not easy to adjust, so as to be fully effective for varying loads and different line characteristics. An adjustment of two interdependent variables is required, *i.e.*, that of the degree of compensation, and the phase, both of which should remain correct at varying loads. A line drop compensator developed by the Metropolitan-Vickers Electrical Company, however, is claimed to be an advance on other compensators. New features permit of an independent adjustment of the amount of compensation and of the phase angle. By the simple variation of resistance it is possible to adjust the phase angle to suit any particular line characteristic and then to vary the compensation separately to suit any variation in the length of the line which may be caused by the switching in and out of certain sections. At all loads the compensator faithfully reproduces the receiving end conditions at the sending end.

The vector diagram 1, Fig. 66, relates to the problem of voltage regulation on a transmission line. The voltage drop can be split up into two components I R, due to the resistance of the line in phase with the current; the other, I X, due to the reactance of the line, leads the current by 90 deg. The resultant of these two drops I Z bears a constant phase relation to the current vector, determined by the line constants, *i.e.*, by the ratio of resistance to reactance, and its magnitude is proportional to the current. It therefore exerts a varying effect on the received voltage for a constant load, depending on the power factor of the load, as shown in diagram 1.

The manner in which a vector voltage is obtained corresponding to the line impedance drop and opposite in phase to it is shown in diagrams 2 and 3.

Diagram 3 represents a network of resistance fed from two current transformers R and B at the sending end. The resistance A C=resistance C D, and E H is twice the resistance A C. The slider P can be moved anywhere along A D and it is evident that the red transformer R will circulate a constant proportion of its total current in E H, while the blue transformer B will circulate a varying proportion of its total current in the resistance E H dependent on the position of P. The direction of the "blue current" in E H will be determined according to whether P is on the left or right of C. The resultant voltage across E H is determined by the resultant current in E H, *i.e.*, the vector sum of the current in E H due to the red current transformer and the current in E H due to the blue transformer. The variations in this resultant current produced by varying the position of the slider P are apparent from the vectors in diagram 2, in which O I_R and O I_B represent the secondary currents in the two transformers. O C represents the fixed proportion of "red current" which flows in E H.

The proportion of "blue current" flowing in E H depending on the position of the slider P will take up a series of values such as O Q, O P, O R, O S, &c., and

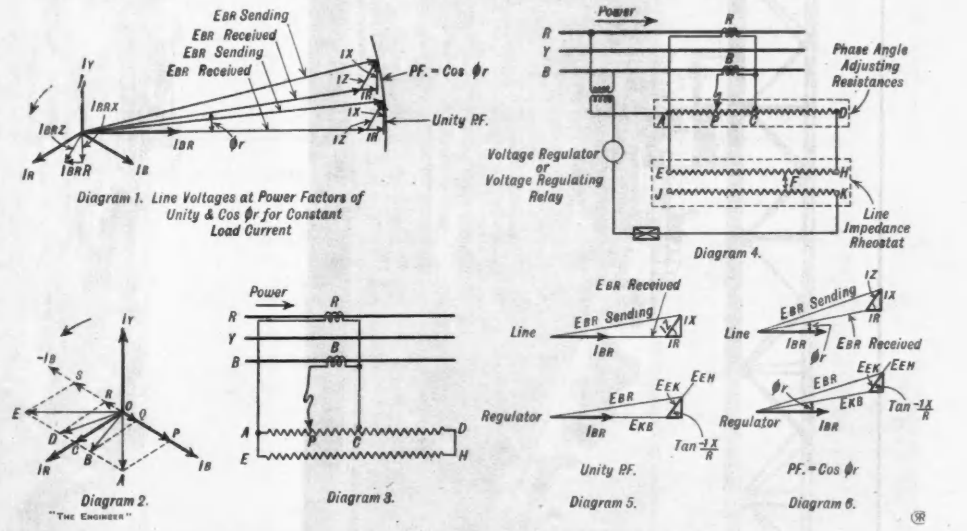

FIG. 66—LINE DROP COMPENSATOR DIAGRAMS

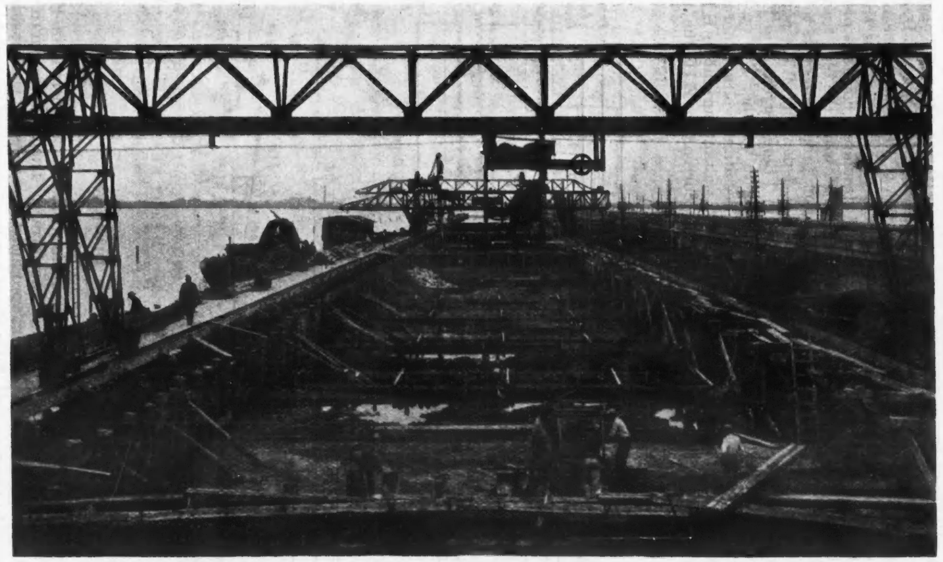
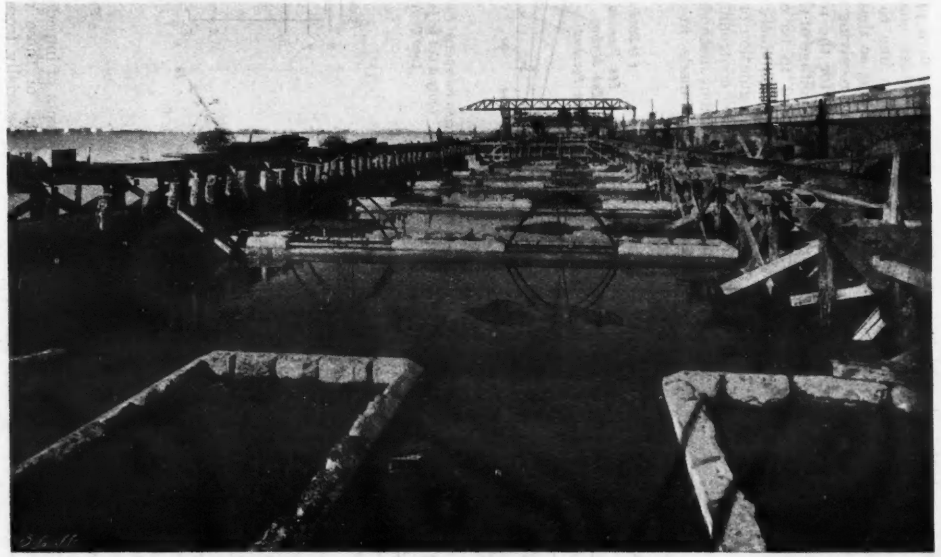
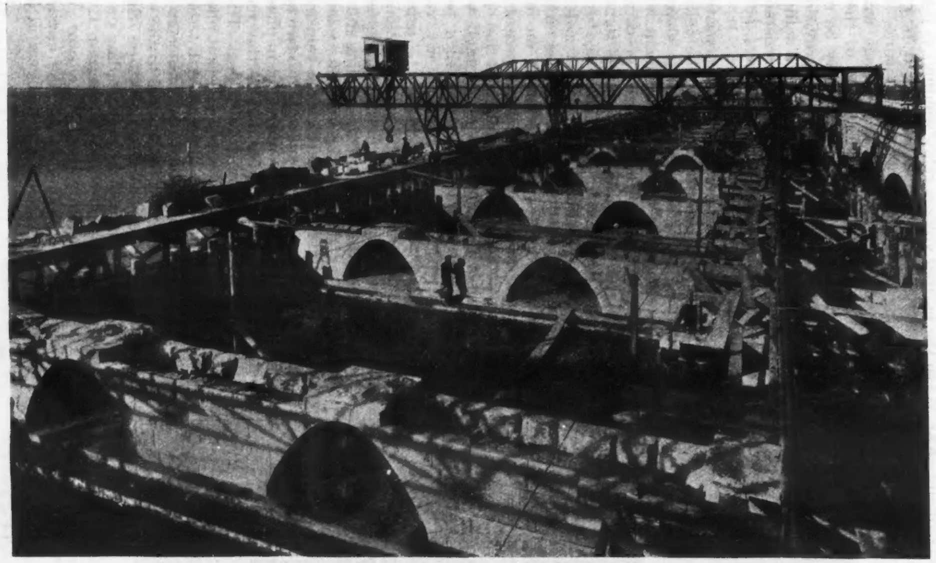
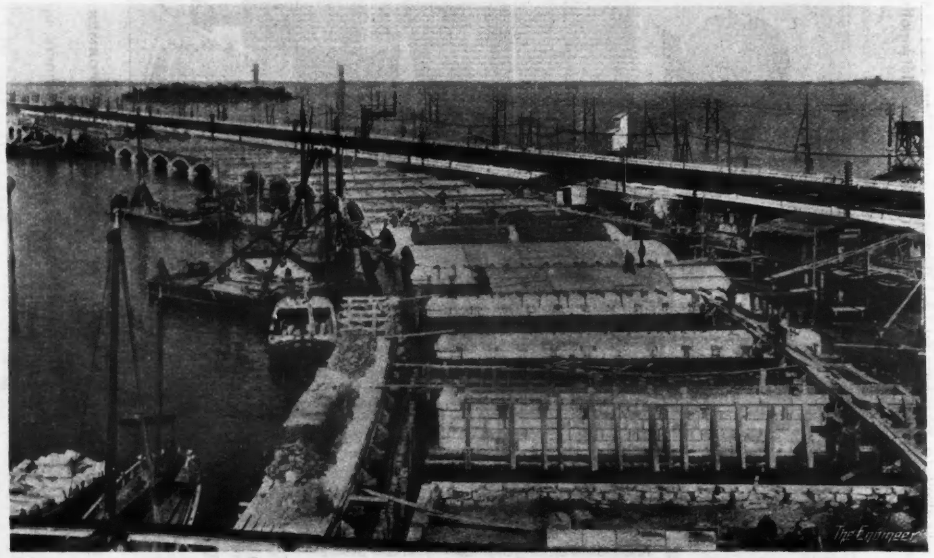
MESTRE-VENICE VIADUCT

(For description see opposite page.)









From these pictures a general impression of the methods of construction adopted can be gained. The space occupied by a group of arches was enclosed within a cofferdam. Outside the cofferdam a wooden staging was erected forming a landing stage for the barges bringing constructional materials and a support for the rails of travelling cranes. As construction progressed each successive section was enclosed within the cofferdams, which were removed as and when the work in each section had reached a height above the water level.

Above :—In this picture work upon the laying of the concrete foundation blocks upon the previously driven piles can be seen. One of the barges bringing constructional materials lies beside the wooden landing stage.

Below :—Operations have proceeded a stage further in this view. A facing of masonry has been laid on the concrete foundation blocks which have been prepared to receive the piers.

Above :—On the straight part of the bridge each of the piers was pierced by three arches. In this view a number of the piers can be seen in various stages of erection.

Below :—Steel centering was placed on top of the piers and overlaid with planks ready for the erection of the brickwork arches. The various stages in the process can be followed in this picture.

the resultant current in E H will take up corresponding positions O A, O B, O C, O D, O E. The line A E is therefore the locus of the resultant current vector in E H caused by moving the slider of coil B in diagram 3. When the slider P is at A, O P in diagram 2 equals O C and the resultant current is O A lagging 90 deg. behind I_{BR} (diagram 1). When P is at C in diagram 3 no current from the blue current transformer flows in E H; hence the resultant current in E H is O C, diagram 2. When P is at D in diagram 3 the "blue current" in E H is reversed and is equal in magnitude to the "red current." Hence the resultant current in E H is O E (diagram 2), 180 deg. out of phase with I_{BR} (diagram 1). By moving the pointer P it is therefore possible to make the phase of the resultant current in E H and consequently the resultant voltage across E H vary from 90 deg. lagging I_{BR} to 180 deg.

At some position of P this voltage may be made exactly equal to the line impedance drop, but opposite in direction, the magnitude of the voltage so obtained being proportional to the load current I_{BR} and to the values of the resistance A C and P C.

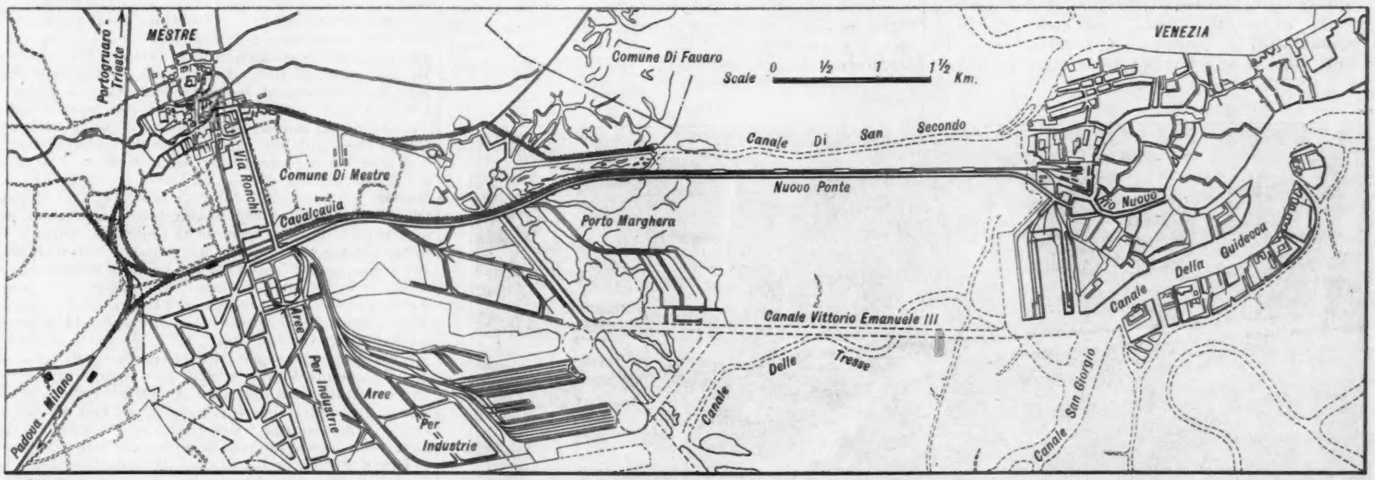
Referring now to the diagram 4, Fig. 66, by the addition of a resistance J K and a slider F a potentiometer device is obtained so that any portion of the voltage across E H may be tapped off, giving a voltage across E K variable in magnitude but not in phase. The resistance J K is equal to half E H, and is so graded that on moving F the resistance between A and K remains constant. Once the position of the slider P has been fixed according to the ratio of resistance to reactance in the line, the voltage across E H is directly proportional to the load and 180 deg. out of phase with the line impedance drop.

By suitable adjustment of F it is therefore possible to obtain a voltage across A K which is exactly proportional to and 180 deg. out of phase with the line impedance drop under all conditions of load and power factor. By subtracting this voltage from the sending end voltage E_{BR} (stepped down by a potential transformer) in the same way as the line impedance drop is subtracted from the sending end voltage a resultant voltage E_{KB} is obtained which is directly proportional to the receiving end voltage under all conditions of power factor and load. If this voltage be applied to the voltage regulating device at the sending end the regulator will operate to maintain constant voltage at the receiving end.

The complete connections for producing this result are shown in the diagram 4, Fig. 66, from which it will be apparent that the voltage E_{KB} is applied to the regulator. Diagram 5 shows the conditions on the line and on the regulator for a load of unity power factor, and diagram 6 the corresponding conditions for a load at some power factor cos φr. From these two diagrams the exact correspondence between the received line voltage and the regulator voltage is evident. The compensator has the advantage of complete flexibility, in that the magnitude of compensation is adjustable independently of the phase of the compensation, and for this reason the combination of resistances A C D is called the phase angle adjusting resistance, while the combination E H J K is termed the line impedance rheostat. The scheme may be equally well applied to an automatic voltage regulator or to a voltage regulating relay. As described, the compensator is only applicable to polyphase circuits, but by suitable arrangements for obtaining the swinging vector corresponding to line impedance drop it can be used on single-phase systems.

The Mestre-Venice Viaduct.

Amongst the many great public works executed in Italy during the last few years, the construction of the Bridge Road from Mestre to Venice ranks among the first in importance, both as a fine piece of engineering, as well as by the consequences it is believed it will have on the life of one of the world's most famous towns. The geographical position of Venice as an island is well known, and requires no further description. The only connection previously existing with the mainland was the railway bridge from Mestre, which was built in the years 1841–45 by the Austrian Southern Railway, Venice belonging at that time still to Austria. The steamboat services of Venice, which take the place of tram services in other towns, provided another connection with the mainland.



"The Engineer"

This plan shows the position of the new bridge on the south side of the railway; the situation of the new canal—Rio Nuovo—in Venice itself; and the means of access from Mestre to the head of the bridge.

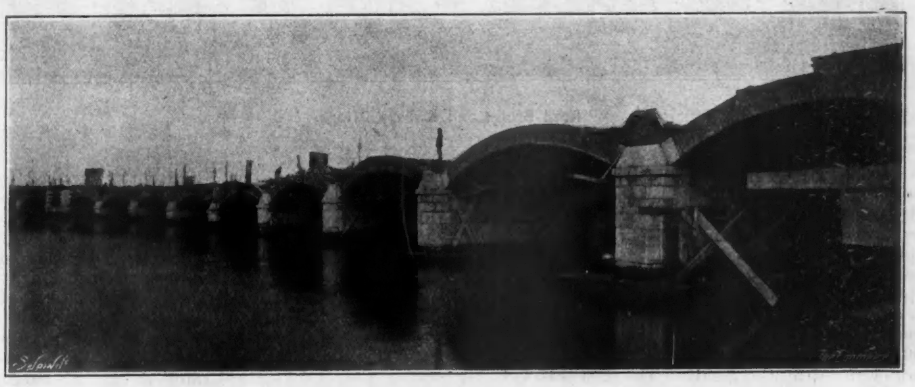
The idea of connecting Venice with the mainland by a road bridge was not new, and, particularly since the opening of the railway bridge, had been discussed on many occasions, without, however, being thoroughly investigated by any responsible body. Amongst the factors which greatly influenced the ultimate decision to build the viaduct was the development of Porto Marghera, which before the war was a stretch of waste land with a few lonely fishermen's huts, and which to-day might be termed the industrial suburb of Venice, laid out on the most up-to-date principles of town planning and having over forty important manufacturing establishments. Venice, with its restricted area, offers no possibility for industrial expansion, and the whole activities in this direction have been transferred to Porto Marghera. It is interesting to note that all previous projects, including the one recommended in 1921 by the Provincial Council, carried the bridge to the north of the railway bridge. But when in 1929 the final decision came to be made, due consideration was given to the position of Porto Marghera, and it was decided to place the viaduct on the south side of the railway bridge so as to bring Venice within closer and more direct reach of Porto Marghera (see map). This decision also facilitated the task of laying out a suitable approach road and terminus square in Venice itself. In this connection the very important question of a central garage had to be considered, and in the selection of a suitable site for its erection allowance had to be made for a sufficient space for a public parking place. The absence of any roads or streets in the usual sense—there are merely lanes and alleys in Venice interconnected by innumerable little bridges—excludes *a priori* the possibility of building a number of garages in different quarters of the town for private and public use. It became therefore incumbent upon the municipality of Venice, which built the Bridge Road, to make the necessary provision for centralising all services connected with the garaging of cars in one building suitably located at the termination of the Bridge Road itself.

Another problem of considerable importance arose in respect of the maritime station of Venice, which had to be brought for obvious reasons into direct communication with the new road, not only for allowing the important road transport traffic to reach the docks and unload alongside the steamers, but also in view of the important passenger traffic of the various steamship lines from Venice. Finally, the speeding up of traffic inside the town was considered. The main artery of Venice is the famous Canal Grande, which begins beyond the railway station and runs in the shape of an inverted S to St. Marks. Its length is 3300 m., and there is a regular service of small steamers running from one end to the other. It had long been felt that an abbreviation of this route would be an improvement. It was therefore decided to cut a new canal, the Rio Nuovo, through the larger section of the inverted S at a point adjoining the terminus square. This new canal has a length of 700 m., and as the larger half of the S is 2400 m. long, a saving of 1700 m. is effected.

Signor Miozzi, Chief Engineer of the Municipality of Venice, who was in charge of the whole construction and execution of the work, and to whom we are indebted for much of the information included in this article and many of the illustrations, blended the requirements with great skill.

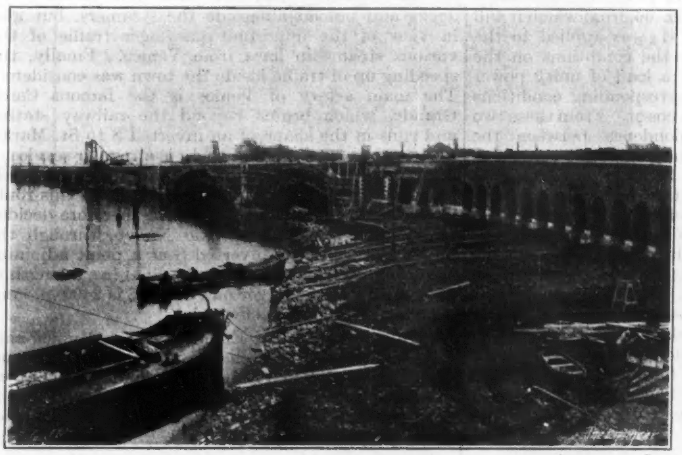
The new road begins at Mestre close to the railway viaduct. The spot has been well chosen, being the junction of all main roads leading to Mestre from various directions. One of these roads will be the Turin–Trieste Autostrada, several sections of which are already built. The Bridge Road runs for about 5 kiloms. on the mainland almost parallel to the railway. Over this stretch it has a width of 22 m. The parapet and footway on the lagoon side occupy 3·5 m., and the footway on the other side 2·5 m., leaving a clear width of 16 m. for motor traffic.

The bridge proper begins at the lagoon. It is composed of a series of arcades which are placed coaxially with the railway bridge and repeat the disposition of piers. An interspace of 2·25 m. is left between the two bridges, partly to facilitate construction and partly to prevent the stability of the railway bridge becoming endangered. This interspace has been covered with a layer of concrete forming a footpath

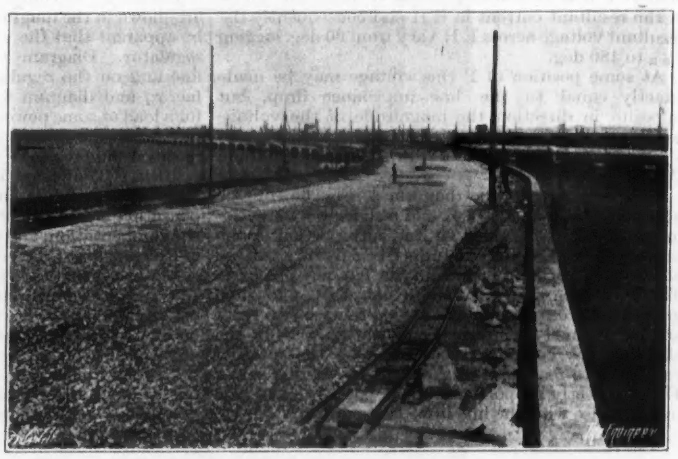


This illustration supplements one of those on page 640 in showing the method of constructing the brickwork arches.

on this side of the bridge, a corresponding footpath of 3 m. width running on the opposite side of the road. The parapet on the lagoon side occupies 0·5 m. The clear width of the road for motor traffic is 15·75 m., the total width of the bridge being 22 m. The viaduct consists of 228 arches built of bricks and cut stone, each arch having a span of 10·63 m. The arches are arranged in groups of five, separated by main piers, 8·65 m. wide. The central arcade has seven arches, and the main piers at each end are 13·73 m. wide. The smaller piers supporting the arches have a width of 1·50 m., and a height of 2 m., and are supported on foundation blocks 1 m. in height and 3 m. in width, which in their turn rest on concrete piles of varying length driven into the bottom of the sea. There are five rows of piles, each containing eighteen piles placed at a distance of 1·09 m. and 1·35 m. from one another. The piers are composed of three parabolical arches of 3·29 m. span and 1·79 m. height, the centre abutments being 3·39 m. wide at their base.

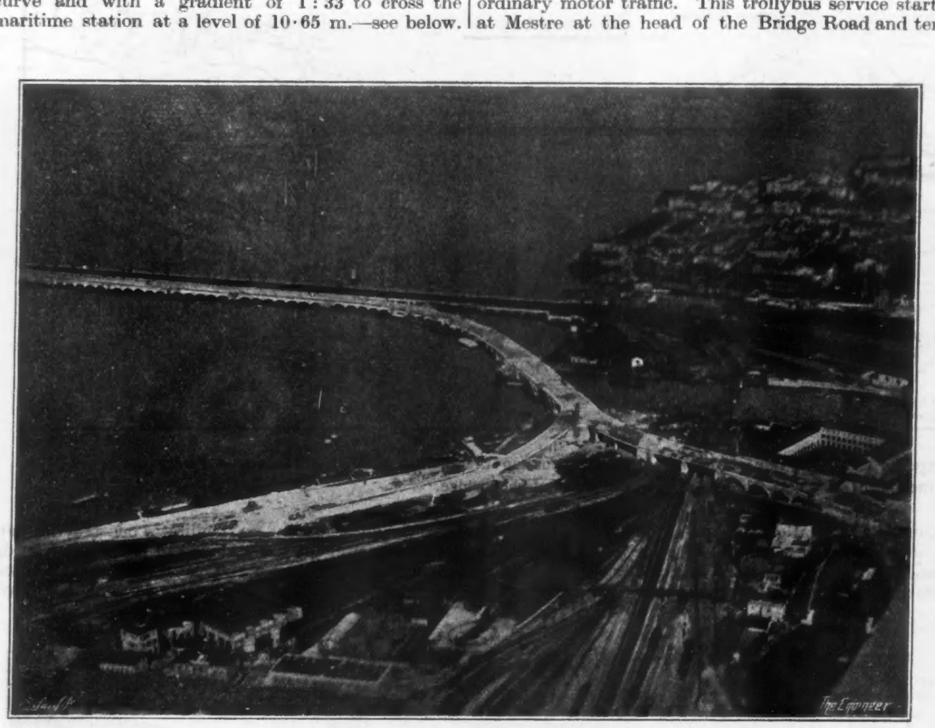


The Venice end of the road. The two arches in the centre of the picture carry the road over the Canale Grande. The viaduct on the right carries a branch road down to the docks.



In this illustration the noble width of the bridge can be appreciated. The bridge proper is completed and the road is being surfaced.

The footway of the viaduct is 3·36 m. above sea level. At Arch 220 the Road Bridge curves away from the railway bridge, crosses the Canal Grande on two arches of 34 m. span each, and continues in a curve and with a gradient of 1 : 33 to cross the maritime station at a level of 10·65 m.—see below.



Road Bridge and Railway Bridge.

A new road leading to the maritime station branches off at the landward end of the canal bridge. The Bridge Road subsequently crosses the marshalling yard on a viaduct of five arches, of which four have a span of 20 m. and the other a span of 9 m. It then crosses the Canal Scomenzera on a viaduct of 20 m. span and reaches with a down gradient of 1 : 33 the terminus square, called Piazza Roma, where the garage is being built. The square covers an area of 40,000 square metres, of which 9000 square metres are occupied by the garage. The area was formerly occupied by a number of old tenement houses of no artistic value, sports grounds, vegetable plots and sheds. As will be seen from the accompanying map, ample accommodation has been left for parking public and private cars on the square.

The new canal "Rio Nuovo," begins at the Canal Grande and adjoins Piazza Roma on one side and the famous Papadopoli Gardens on the other side. The whole quay of the Canal Grande between the Canal Scomenzera and the Rio Nuovo, a distance of 700 m., has been newly constructed and landing-stages for the steamer service, motor boats, gondolas, &c., have been provided. The Rio Nuovo has a length of 700 m. and an average width of 15 m. Its construction necessitated the building of a number of new bridges and other structural alterations, all of which were carried out without interfering with any building of artistic or historical interest.

The agreement between the Government and the municipality for the construction of the Bridge Road stipulated that there should be an electric tram line to Mestre. It was found, however, that such a tram line requiring a double track would occupy 7 m. width, reducing the available space for motor traffic to 9 m., which was considered to be insufficient. To suit local conditions, the best solution was found in an electric overhead trollybus service, which allows perfectly free movement without interfering with ordinary motor traffic. This trollybus service starts at Mestre at the head of the Bridge Road and terminates in Piazza Roma. Current is supplied from the transformer sub-stations at Venice and Mestre through mercury vapour arc rectifiers.

The garage is in course of construction, and will be built in two stages, the first of which is already completed. It has a length of 100 m. and a height of 23 m., and contains, besides a basement floor, five upper floors. The basement floor is reserved for cycles, motor cycles, repair and workshops, stores, &c. The upper floors are reached by a ramp of 4 m. width, a second identical ramp serving for outgoing cars. The average width of the curves is 8·60 m. and the gradient 1 : 16. The front part has accommodation for 900 cars, and the rear part of the building, when completed, will have accommodation for the same number of cars, so that on completion a total of 1800 cars will be able to park in this garage. The building on completion will have a floor space of 50,000 square metres. The erection of the front part necessitated the excavation of 4500 cubic metres of earth, and over 7000 cubic metres of concrete and 700 tons of iron were required.

The first foundation pile for the construction of the bridge was driven at the beginning of July, 1931, and the completed Bridge Road was opened for traffic on April 25th, 1933—after twenty months. The total cost amounted to 80 million lire (£1,230,000). On page 640 and accompanying this article a number of photographs illustrating the construction of the bridge are reproduced.

SIXTY YEARS AGO.

In our issue of January 2nd, 1874, some authentic information is to be found concerning the history of the first Bessemer steel rail—which incidentally was also the first cast steel rail—ever laid down on a railway. The information was contained in a letter to the editor from Mr. Robert F. Mushet. In the early part of 1857 Mushet cast some blooms of Bessemer steel for the Ebbw Vale Iron Company. Some of these blooms were rolled into double-headed rails at the company's Victoria Ironworks. One of these rails was sent to Derby Station, where it was laid down at a point of maximum traffic. The rail was still in service in 1867, and on December 26th of that year Mushet wrote to Mr. John Crossley, of the Engineer's Office, Midland Railway, asking how many trains passed over it each day and whether the railway company would dispose of the rail to him. Mr. Crossley replied that about 250 trains passed daily over the rail and at least the same number of detached engines and tenders. He was disinclined to recommend the sale of the rail, but he promised Mushet that if it were ever taken out he would be given the refusal of it. On June 16th, 1873, Mushet again wrote to Mr. Crossley, who replied, expressing his regret that about ten days before Mushet's letter had been received the rail had been taken out and used up. Mushet thought that it was a great pity that this historic rail had not been preserved. A hundred years later, he remarked, it might have been worth thousands of pounds and have been an object of interest and curiosity. He called attention to the fact that the rail had had a life of sixteen years and that during that time about one and a-quarter million trains and an equal number of detached engines and tenders must have passed over it. He did not know how long an iron rail placed at the same point would have lasted, but its life would certainly not have been sixteen months, probably not six months. . . . Even in those days efforts were being made to improve on Bessemer steel for railway track work by the devising of a practical and economic method of alloying manganese with iron. Processes by Prieger and Henderson, both founded on the simultaneous reduction of a mixture of pulverised iron and manganese ores, had been tried, but in both cases the output was small and the fuel consumption enormous. In the issue above referred to we noted a new process devised at the Terre Noire Ironworks in France. Under this method filings or turnings of iron, steel, or cast iron were mixed with pulverised ores containing manganese, tungsten, or titanium. The mixture was thoroughly moistened with a solution of ammonia or slightly acidified water and was then compressed in an iron mould. A large amount of heat, it was stated, was thereby evolved, and on opening the mould some hours afterwards it would, it was asserted, be found to contain a very hard mass, which could be broken into fragments by means of a hammer. The fragments were subsequently treated in a blast-furnace. Alloys containing anything from 25 to 50 per cent. of manganese or other percentages of tungsten or titanium could be produced in this manner, so it was stated. The temperature required in the furnace, it was noted, was very high and the blast had to be injected very hot and under great pressure. Special provision had therefore to be made to enable the furnace to withstand these trying conditions. The fragments were deposited in a crucible composed of carbon, lime and manganese, and the furnace itself was built of very hard fire-clay bricks lined with lime, manganese, or pure alumina.

Railway and Road Matters.

The traffic receipts for the forty-ninth week were noteworthy in that the Great Western joined the Southern in reporting an increase in the total receipts for the year. The L. and N.E.R. was, moreover, only £170,000 down. The L.M.S. decrease was £503,000 for the year.

The statistics for the German State Railways give an excellent record as to railway accidents. In the years 1930, 1931, and 1932 the number of passengers killed in train accidents was three, one, and three respectively. There was, too, an improvement each year in the fatalities to passengers, other than in train accidents; those figures were 109, 91, and 56.

During shunting operations on the morning of Tuesday, December 19th, a goods brake van ran back in the wrong direction at Hellifield Goods Yard box on the former Lancashire and Yorkshire Railway. Unfortunately, a goods train from Manchester to Carlisle was in the section, and it collided with the brake, causing the engine of the goods train to be derailed and thrown down an embankment. The driver and fireman were killed.

The retirement at the end of the year of Mr. A. S. Bailey, the managing director of the Metropolitan-Cammell Carriage, Wagon and Finance Company, calls for mention in this column, inasmuch as he was essentially a railway man. Mr. Bailey started in the Lillie Bridge shops of the Metropolitan District Railway in October, 1883, but gained most of his practical experience at Nine Elms, on the London and South-Western. After two years as an inspecting engineer for Sir Alexander Rendel, he went, in 1897, to the East Indian Railway, where, among other events, he superintended the construction of the first locomotive to be completely built in India. From 1904 to 1912 Mr. Bailey was chief mechanical engineer of the Bengal-Nagpur, and on his return to England joined Cammell, Laird and Co.

The Railway Returns for 1932 show that during that year the locomotives of British railways consumed 11,699,515 tons of coal, and 31,476,474 pints of lubricating oil, as compared with 12,266,825 tons and 33,209,776 pints respectively in 1931. The amount of coal consumed per engine-mile by steam locomotives was 52·39 lb. in 1932, and 53·12 lb. in 1931, whilst the average of the lubricating oil was 6·28 pints per 100 engine-miles in 1932, and 6·41 pints in 1931. There was a decrease in 1932, as compared with 1931, of 7·15 per cent. in the total wagon miles worked. The average number of wagons per train decreased from 34·12 to 33·57, but the proportion of the loaded wagons per train rose from 66·44 to 66·53 per cent. The average wagon load for all descriptions of traffic decreased from 5·50 to 5·42 tons, and the average train load from 124·73 to 121·00 tons.

The introduction of colour-light signals, wherein the day indications of "danger," "caution" and "clear" are given by red, yellow, and green lights, as at night, drew attention to the comparative powers of the light given for the night indications of the customary semaphore signal. That was a point made by the 1927–1930 Automatic Train Control Committee, and greater attention is now being paid to signal lamps. The tail lamps carried by the last vehicle of trains now need more consideration in view of the abolition of the side lights which were additionally carried. The two firms principally engaged on the manufacture of railway lamps have been the Lamp Manufacturing Company and the Railway Supplies Company, and as these have now recently been amalgamated, the desirable improvements in signal and train lamps should be more readily and effectively obtained.

In announcing its works and rolling stock programme for the year 1934, mentioned herein on December 15th, the London, Midland and Scottish Company says that with the completion of that programme the company will have spent £100,000,000 on large replacements and improvements. The best index, it says, of the increased efficiency which has been secured by this policy is provided by the locomotive position. While 2500 new locomotives have been built or ordered, the corresponding number of engines withdrawn from service is 4800, indicating greater efficiency not only of the engines themselves, but of the method of their employment so as to obtain the maximum use of each locomotive. The number of different types of locomotive in the company's service has been reduced from 393 to 204, while the number superheated has been increased by 2000, or more than doubled. These changes have enabled heavier trains to be hauled at higher speeds, and reduced coal consumption and repair cost per mile.

The terrible disaster of Saturday evening last, near Lagny, on the Eastern Railway of France, by which some 200 passengers lost their lives, has revived an old saying that there always is a bad railway smash at Christmas time. In the late 'seventies it did really seem as though that was so. The Shipton-on-Cherwell disaster of December 24th, 1874, when thirty-four passengers were killed as a result of a broken axle, began this series. An unusual snowstorm led to the double collision and the loss of fourteen lives at Abbotts Ripton on January 21st, 1876, whilst at Arlesley, on December 23rd, 1876, four passengers were killed, when an express overran the signals and collided with a goods train. The Tay Bridge disaster, with its seventy-three fatalities, came on December 28th, 1879, and the series ended on December 21st, 1880, when, at the Midland station at Leeds, an outgoing train was allowed to leave on the arrival line and in the head-on collision that resulted four passengers were killed. For a spell of nineteen years the association of serious railway accidents with Christmas found no warrant, and then, on December 23rd, 1899, the up Newhaven Continental boat train, when standing at Wivelsfield in a dense fog, was run into by an express from Brighton to Victoria and five passengers killed. In none of these six cases, though, was the excess of traffic at Christmas the main nor even a contributory cause, and it was not until, and as recently as, December 24th, 1910, that, at Hawes Junction, on the Midland Railway, the heavier traffic of the Christmas of that year led to two light engines, coupled together, being left on the down main line and overlooked. These were run into by an express and twelve passengers lost their lives.

Notes and Memoranda.

Copper containing about 2·5 per cent. of beryllium is being used in America as an alloy for making small boat propellers. It is said to permit a reduction in the thickness of the blades by 25 per cent.

A vertical lift bridge has been built at the freight wharf of Kawasaki Harbour, for the South Manchuria Railway Company, entirely by arc welding. It has a span of about 69ft. and a lift of 30ft. The job required the making of over 4000ft. of welded seams, but the total cost was only £1300.

The Kommerer Coal Company, Wyoming, recently had to build a bridge across a gully in order to get coal from one of its pits to the loading yard. It had, says *Electric Welding*, on hand a considerable accumulation of scrap 10in. steel pipes and rails from closed mines. The engineers designed and built a bridge out of this scrap by welding. The bridge is 393ft. long, supported about 100ft. above the deepest part of the gully, and capable of carrying the coal trains. As the scrap material had all been written off the books, the money cost of the bridge was little more than that of the electrodes, labour, and the current used.

A new method of producing X-rays by using heavy and relatively slow-moving particles of electricity instead of the usual fast-moving light electrons, has been discovered by Dr. W. M. Coates, of the University of California. His method is to use mercury ions. The energy obtained from these particles (which have a low velocity by comparison with electrons) is very large and is given in small repeated acceleration. Positive mercury ions at 2,400,000 V are allowed to strike targets of various elements, thus producing X-rays. It was found that these heavy ions produced ten times as many X-rays as do 3000 V electrons.

In comparing the planer and the milling machine, we should, says Mr. F. E. Cardullo, in *The Iron Age*, compare only machines of modern design. Most planers and many milling machines now in use are of obsolete design. Under favourable conditions, a planer of medium or large size will remove metal from work of suitable size at a faster rate than a milling machine, and less work is expended in removing the metal, because tools of better form may be used, coarser feeds may be employed, the planer tool does not distort the chips as much as the milling cutter, it does not cut the chips into fine pieces, and it does not abrade the work with the chips. When a relatively small proportion of the surface of the work is to be finished, the planer usually works at a disadvantage, using more power and doing the work less rapidly than the milling machine.

In an article on "Gas Fuel for Electrical Generation," *Heat Treating and Forging* states that a few years ago most of the steam-powered generating plants in Southern California were considered as stand-by units for the hydro-electric systems, but this position has now been reversed. The present tendency toward steam rather than hydro-electric generation is due largely to improvement in steam plant efficiency and in part to the use of the large available supply of fuel—natural gas. The demand for gas for domestic use is very seasonal, being high in the winter and low in the summer. The electric load of the Edison Company is high in the summer and low in the winter. This condition, combined with the fact that there is more stream flow hydro-electric power available in the winter, presents the possibility of a high annual load factor for gas transmission lines serving the dual purpose of supplying both gas and electric utilities.

It is of importance for practical purposes to know the magnitudes of the experimental errors to be expected in the analysis of coal and coke. It is only when these are known that it is possible to state whether differences in results are due to the inevitable experimental errors, or to a true difference in the substances under examination. A report just issued by the Department of Scientific and Industrial Research deals with the general principle of the Probability of Errors and its application to analytical practice. The probable error of the various routine analytical determinations for coal and coke are deduced and their implications discussed. The figures on which these results are based are tabulated and the formulæ used are given. The bulk of these figures were obtained from an investigation carried out jointly at Newcastle upon-Tyne by the staff of the Coal Survey Laboratory of the Departent of Scientific and Industrial Research, and the staff of the Northern Coke Research Committee. A number—sixty-four—of repeat determinations for each test was carried out on one sample of coal or coke. Similar series of analyses on pure chemical substances were also carried out to determine to what extent, if at all, the discrepancies observed were due to a lack of uniformity in the samples of coal or coke. The report can be obtained from H.M. Stationery Office, price 9d.

It is well known, says *Nature*, that the windows of houses exposed to the sun's rays act like heat traps. They permit most of the radiant energy from the sun to pass into the building, but block the low-temperature radiation from inside surfaces passing out. Science Service has issued a report of results obtained by research physicists of the American Society of Heating and Ventilating Engineers in their laboratories. Formerly it was thought that glass absorbed only about 10 per cent. of radiation at low temperatures. The experiments show that a temperature of 550 deg. Fah. must be reached before any appreciable amount of the radiation passed through plate glass. Even at 1000 deg. Fah., only a small amount passes through. Glass obviously acts as a very efficient heat trap, and this has to be taken into account by the ventilating engineer. In many modern buildings, a side built almost entirely of glass is exposed to the sun's maximum radiation. On a hot summer day, the glass permits the heat from the sun to enter and practically none of it escapes. Indoors, therefore, it becomes unbearably hot. The cost of keeping a building of this nature cool is practically prohibitive. Awnings which deflect the light and are hung outside the windows are perhaps the most efficient. Shades and blinds are of little value as the heat passes through the glass, heats the blind, and is convected upwards, thus heating the room. Tests proved that there is no practical difference in efficiency between clear and coloured glass.

Miscellanea.

A pressure creosoting plant is to be put up at Prince Albert, Saskatchewan, at a cost of some 1,000,000 dollars.

The Nine Locks Ironworks, Brierley Hill, which have been idle for eight years, have been reopened with a good order book.

An aerodrome is to be made at Southend on an area of 157 acres, which has been acquired by the Council at a cost of £20,000.

The new ship of the Orient Steam Navigation Company, which is to be built by Vickers-Armstrong, will be slightly larger than the "Orontes."

The works of Ley's Malleable Castings Company, and Qualcast, Ltd., are to be considerably extended, and employment for another 1000 men thus provided.

It is proposed to construct a bridge across the First Narrows of Burrard Inlet, Vancouver, at a cost of about £1,200,000. The bridge will have a span of 1500ft.

The Tyne Improvement Commissioners are considering the question of fitting anti-coal-breakage appliances at No. 4 and No. 5 staithes at Whitehill Point, North Shields.

The Acklam Steel Mills of Dorman, Long and Co., which have been idle for three years, are being re-started. Two more blast-furnaces have also been relighted at the Cleveland Ironworks.

It is claimed that the 715 horse-power Wright Cyclone F engine used by Colonel Lindbergh in his recent flight is the lightest engine in the world. It is said to weigh 1·22 lb. per horse-power.

In November, the second section of the First State Ball-bearing Plant in Moscow was opened, thus completing the whole enterprise, which is, it is claimed, now the largest of its kind in the world.

Although the new bridge at Middlesbrough, which has cost £600.000, was opened to traffic on Wednesday. the 20th, it will not be formally opened, by the Duke and Duchess of York, until February 28th.

It was reported to the Tyne Commission at Newcastle that the coal and coke shipments for November were the largest monthly shipment for 2½ years, and that the total for this year of 11,791,521 tons was 215,000 up on last year.

Very rich copper deposits have been discovered in the Djez-Kargan region, in the Kazak Republic. The reserves are estimated at 2 million tons, and the copper content is so high as to make it the cheapest copper obtained in the Soviet Union.

A winch for the French trawler "Jutland," which, when she is launched at Frederikshavn, will be the largest of her kind afloat, is being supplied by James Robertson and Co., of Fleetwood. The winch weighs 23 tons and will deal with 1200 fathoms of steel cable.

Another instance of "ship surgery" is to be carried out by Messrs. Palmers, of Hebburn-on-Tyne, who have been awarded a contract to lengthen s.s. "Doric Star" (10,441 tons). This vessel is to have her present fore-end cut away and a new portion, 30ft. long, added. This will include a bow of the Maier form.

The demands at the electric power stations of Birmingham during the first week of December broke all records with a total load of 200,000 kW, as compared with a maximum of 177,000 kW last year. On one day during the month as much as 2,656,000 units were produced, an increase of 15½ per cent. over the corresponding record of last year.

A sum of 6 million roubles is to be spent by the Soviet Government for the erection of three factories for the production of chemical fertilisers. Two of the factories will be operated in connection with the Kuznetsk and Magnitogorsk iron and steel works, utilising waste coke-oven gas. The third factory is to be constructed in Chirchiky, near Tashkent.

According to figures published by the *Northern Miner* (Toronto), twenty-five new gold mills are now under construction by Canadian mining companies, the completion of which will add over 6000 tons daily to the industry's milling capacity. In Ontario, which had eighteen producing mines on June 30th last, twenty-eight or thirty mills are likely to be in operation next June.

The erection and equipment of a patent fuel plant at the Bulgarian State collieries at Pernik have, says the *Iron and Coal Trades Review*, been completed, and the first briquettes produced. Preliminary trials of the plant are reported to have been very satisfactory. The patent fuel made will be used by the Bulgarian State Railways, which will now become independent of foreign supplies.

According to *Flight*, the directorate of Aeronautics at the U.S. Department of Commerce has announced plans for the establishment of 2000 additional landing grounds in the United States; 10,000,000 dollars of the civil works funds have been set aside for this purpose. The main object is to extend the Federal Airways system to all parts of the country at present not served by airways, and thus to increase the safety of private flying.

The recent change-over from D.C. to A.C. electric supply at St. James's Palace has necessitated some alteration of the Siemens' telephone system which has been in use there for some years. A rectifier has now been installed for "floating" the battery, and while the alterations were in progress it was decided to renew the battery also. Siemens Bros., Ltd., have, therefore, installed a set of six chloride cells of sealed-in Planté type.

Blyth, Northumberland, appears certain to eclipse all records in coal exports this year. The highest figure hitherto attained was in 1929, when 5,750,000 tons were shipped. At the end of the first week in November this year the total had reached over 4,760,000 tons, and weekly outputs in the neighbourhood of 150,000 tons were higher than ever before. The month of November witnessed the Blyth Harbour filled with vessels awaiting coal, with the result that the Harbour Commissioners are having to push ahead their extension schemes as fast as possible.

⁂ *No undertaking can be given to return drawings or manuscripts; correspondents are therefore requested to keep copies.*

The Metallurgist.

THE DECEMBER NUMBER OF
THE METALLURGICAL SUPPLEMENT TO
"THE ENGINEER" ACCOMPANIES THIS ISSUE.

Development of the Parsons Steam Turbine.

The steam turbine is one of the landmarks in engineering industry. Coming at a time when the electrical age was beginning, it both made large scale electricity supply possible and was made by it. The first turbo-generator made under Parsons' patent of 1884 developed about 7·5 kW; single turbo-generators over 100,000 kW capacity are now running. The present estimated value of Parsons turbines alone is £152,000,000, the figures for marine and land turbines being £92,000,000 and £60,000,000 respectively. Nothing to equal that rapid extension of value and dimensions has ever happened before.

Before the death of Sir Charles Parsons we had taken preliminary steps for the publication of a series of articles on the development of the Parsons turbine to celebrate its jubilee. The preparation of that series has been delayed by one cause and another, and can now not benefit by his personal supervision, but if it lacks anything of the vivid touch which he might have given, it still remains a most fascinating history. We need scarcely say that the publication of the series, which will begin on January 5th, 1934, will occupy many weeks, but the history is one in which every engineer takes a deep interest and pride, and we have no doubt that our articles will be widely read and appreciated.

CONCRETE FOR SPECIAL PURPOSES.

THERE has been in the past few years a noticeable increase in the attention given by engineers and research workers in all parts of the world to the problem of producing cement more suitable for certain special purposes than the ordinary standardised Portland cement. During the past decade the contributions to technical literature on the subject of specialised cements have been considerable. The matter has also been raised at several congresses and technical meetings, both of international and national or local character; for instance, the relative suitability of Portland and trass or Pozzuolanic cements for work in sea water was discussed at length by the International Navigation Congress at Venice in 1931. More recently interest has been focussed on the subject during the meeting of the International Commission on Large Dams in Sweden in July last, and in the course of the informal discussion at the Institution of Civil Engineers on November 15th on the desirability of introducing more than one standard for Portland cement and a standard for Pozzuolanic cement. On both of these occasions attention centered on the necessity of obtaining and using for large dams and other structures subject to unilateral water pressure a cement specially suitable for such works. Mention of some of these problems has also been made in the series of articles on the Scandinavian Congress and on Hydro-electric Power Plants in Sweden which have recently appeared in this journal. It seems therefore opportune briefly to review the situation.

Much more attention has hitherto been given to the problem abroad than in this country, and, although some important researches have been carried out in Great Britain on the behaviour of cements under special conditions, the quantity of cement for constructional purposes, other than normal Portland cement, at present used or produced in this country is relatively very small. Blast-furnace slag cement—known in this country as Portland-blastfurnace cement—is the only alternative to normal Portland cement at present covered by a British Standard Specification, and it is not produced in Great Britain on a large scale—relatively, at any rate, to the production of standard Portland cement. Valuable research work has, nevertheless, been carried out by the Building Research Board and by the Committee of the Institution of Civil Engineers on Deterioration of Structures in Sea Water. On the Continent generally Pozzuolanic and trass or quasi-trass cements are largely employed, not only for sea works but for other forms of construction and frequently as an addition to Portland cement. A cement of trass character, known as gaize, has in recent years been used with apparent success for harbour works in France. A new and comprehensive cement specification is proposed by the French standardising body, L'Association Française de Normalisation. An article in a recent issue of *Revue des Materiaux de Construction et de Travaux Publics* indicates that the draft of this specification covers a very full range of hydraulic cements embracing nine different groups or types, and no less than thirty-six grades. The production of a suitable cement for large masses of concrete is one of the most important problems to be solved at present in connection with the construction of large dams. Normal Portland cement as now produced in this country possesses certain characteristics which render it not ideally suitable for dam construction. The efforts of manufacturers and chemists hitherto seem to have been directed in the main to the increase of the strength of the cement and concrete in the initial and early states and to the perfection of methods of fine grinding. The considerable heat rise of modern fine ground cement in setting and hardening is often a source of trouble when large monolithic masses of concrete are formed in a dam structure. Furthermore, the partial solubility of normal cement in water, particularly in acid waters, is sometimes a cause of rapid deterioration in concrete structures exposed to water pressure and percolation. American chemists and engineers have met with considerable success in the production of low-heat cement for use in the construction of the Hoover and Pine Canyon dams in the United States, but, as the content of free lime in the American special cement is greater than in normal Portland cement, it is possible that the solubility in water of the former may even be greater than that of ordinary Portland cement, and, so far as we are aware, the specification for the cement used on these works does not embody any stipulations concerning its solubility. The *Engineering News-Record*, commenting a few weeks ago on the proposed French cement specification, mentions the dissatisfaction of many American engineers with the present single-standard specification. "Consideration of this wide range of hydraulic cementing materials," observes the editor referring to the specification, "tends to support the growing belief that a particular cement is not necessarily best adapted to different service conditions, and that proper conservatism need not interfere with new developments in materials." We understand that experimental work on the production on a commercial scale of a low-heat cement is now being carried out by cement manufacturers in this country. As far as we are aware, however, this product is not likely to have a greater resistance to the action of water than normal Portland cement, and in this respect the limited scope of these researches is to be regretted. Attention has, however, been specially directed in the past few years to this matter of solubility by engineers and chemists in Scandinavia, where the water held up by dam structures is usually of an acid character. The cement manufacturing industry in Sweden has carried out an important series of researches to investigate the possibility of producing commercially a cement specially suitable for structures subjected to the unilateral pressure of water, and, in particular, water of an acid character, which at the same time should generate as little heat as possible during setting and hardening. These investigations were made at the request of civil engineers in Sweden engaged on dam construction, and they have been so far successful that, early in 1932, a cement, richer in silicate than ordinary Portland cement, and known as silicate cement, was placed on the market. It is now being used in Scandinavia in the construction of dams, including the barrage and other works of the Vargon hydro-electric power station which we described recently. In Norway one of the dams visited by members of the International Congress on Large Dams in July last—that at Gronvollfoss on the Tinne River—has been built with a special cement, having a low content of lime and therefore relatively low solubility in water, which was manufactured in a special plant erected near the site of the work.

At the meeting of the International Commission on Large Dams at Trollhattan in July last, it was resolved that a report on cements most suitable for use in the construction of dams should be prepared for presentation at the next meeting of the Commission. Following on this resolution it has been proposed to form a special international committee to consider the subject in detail and to collate the results of experiment and research now being carried out by cement manufacturers, engineers, and chemists in all parts of the world. It is suggested that the various national committees of the Commission should be asked to arrange for further research work in their respective countries, and in due course to communicate the results to the International Committee in Paris. In the course of about two years it may be possible, if this procedure is carried out, to reach some authoritative and valuable conclusion on the subject. It is satisfactory to know that something is being done in this country, even if only on a limited scale, to meet the needs which we have indicated thus briefly, but it seems to us that more is required if British industry is to retain the high position it now holds in the production of high-class cements. There is little doubt that the demand for one or more additional forms of cement for special purposes is sufficiently great to justify production on a commercial scale by cement manufacturers.

Ill-Informed Railway Criticism.

WE have more than once had occasion to express regret that so many members of the general public rely upon the popular Press for their opinions on specialised questions of the day. That tendency is particularly unfortunate when the subject is one on which the papers themselves, because of their lack of the necessary inner knowledge of the facts, form their conclusions from superficial appearances. In no direction is this more manifest than in relation to railways, concerning which there has been an agitation recently for larger wagons and for the fitting of vacuum brakes to all freight trains. Actually, the demand for the bigger wagon was begun, in the journal now in our mind, a couple of years or more ago, when there was an agitation for a wagon of 40 tons capacity! That was based on the experience of the writer of those articles on South American railways. Conditions there, and in the United States and Canada, are altogether different from those in Great Britain; moreover, the railways of Germany, France, Italy, and other Continental countries use, like the British railways, the smaller wagon. The railways of North and South America call for long hauls of consignments in bulk. British railways, on the other hand, have to cater only for comparatively short journeys, and such bulk consignments as are common in America are very exceptional here. A good deal of the freight business done by British railways is in small lots. The American railways do not touch these as individual consignments; they are handled by the Express companies, which collect, transport in their own trucks, and deliver them, and the only duty of the railway companies is to convey the Express companies' trucks. The competition of the road transport interests makes the need for the big wagon for general merchandise less than it was. The railway companies dare not wait until there is sufficient traffic on hand to fill a wagon. Hence, in order to retain the traffic, wagons are dispatched not fully loaded. In this relation we are, of course, discussing general merchandise, and not the transit of mineral traffic; for the latter, a 20-ton wagon is now the universal standard. For merchandise the standard wagon is one of 12 tons capacity, and although our daily contemporary made a sarcastic reference to the London, Midland and Scottish having ordered 2000 wagons of only 12 tons capacity, that seems sound policy when the Railway Returns show that the average load for a wagon containing general merchandise is less than 3 tons.

Continuous brakes for freight trains are less universal than the big wagon. Their introduction on to the railways of North America came almost naturally, as that country originated continuous brakes for passenger trains. But such equipment on freight trains was more necessary there than in this country. Owing to the more generous dimensions of the American structure gauge, the locomotives there were bigger and more powerful than those in this country, and they were capable of hauling much bigger loads and longer trains than were employed here. Thus a need for continuous brakes arose. The greater length of the American train was a serious matter for the railway companies, as it necessitated a large number of brakesmen to accompany each train in order to apply the hand brakes on individual vehicles as required. It is to the credit of British railway companies that they saw one serious objection to the adoption of continuous brakes on freight trains. That was the greater danger that would attend the occupations of the shunter and the goods guard, since they would have to pass between the buffers of adjoining wagons in order to couple and uncouple the brake pipes. As the American railways have automatic couplings, there should be no necessity for men to go between the wagons to couple and uncouple, but in such a normal year as 1927 forty-eight men were killed and 1325 injured when engaged in coupling movements, and twenty-one were killed and 398 injured in coupling or uncoupling the brake pipes. In this country, although automatic couplings are the exception, there were in that year only four killed and 418 injured. But when the newspapers urge British railways to equip their freight wagons with continuous brakes they are preaching to the converted. That has been the policy for a good dozen years, and, from time to time, our pages have recorded how the companies have provided so many wagons equipped with the vacuum brake, and the number of freight trains of the two classes—No. 1 freight with a large proportion of the wagons braked and No. 2 with a lesser proportion. Trains wholly or partly fitted with the vacuum brake have two particular merits; they can travel at a high overall speed, seeing that they can postpone deceleration on approaching a stopping point longer than can a non-braked train, and they can travel with greater safety because of a more ready stop in the event of danger, and because they will automatically be pulled up should a coupling fail. The greater use of braked trains to-day is to allow for the just-mentioned greater overall speed, so as to help towards quicker journeys for consignments, and thereby to meet road competition. Especially is this advisable where long distances are concerned, as therein the manufacturer and trader must be shown that the railway can deliver as readily and as speedily as can road transport from door to door.

Criticism of the railways is common because everyone uses the railways and because it is so easy to make. No one seems to think that it is necessary to be an expert in railway matters. People who have never heard of traffic density will abuse our companies for not running more trains, and who have never looked at a loading or a structure gauge will ask why they do not see on our lines locomotives as big as those found in America. They speak, too, as if British railways were inert and unprogressive; yet if they would throw their minds back a score of years, even a decade, they would be able to identify a dozen directions in which obvious progress had been made, and they, of course, would miss all the unseen improvements which the companies have carried out. In one sense the railways have brought the trouble on themselves. Not until within the last few years did they take any pains to let people know what they were doing. They, so to speak, threw Bradshaw at the head of the public, told it to select its train, and leave the rest to them. Now they are paying a great deal of attention to publicity—witness, for example, the triumphant march of the "Royal Scot"—and, as years go by, we may hope—not very hopefully—that the public will know so much about railways that ill-informed criticism will no longer be heard.

Shipbuilding.

The end of 1933 finds us with about 20,000 more men employed in British shipyards than at the moment of deepest depression in 1932; but we shall still have about 50 per cent. of our recognised (insured) shipyard workers unemployed. This deplorable percentage is worse than it looks, for since 1920 the number of men attached to the industry has been reduced by one-half. In other words, four times as many men were at work in 1920 (and in 1913) as there are at this moment. However, the present movement is definitely upward, and promises to be progressive over a long period. We are on the way back to prosperity, though we may never employ quite so many men in shipbuilding as in past years.

In November British shipbuilders secured orders for more than 100,000 tons of new merchant shipping, plus some notable contracts from the Admiralty, and many more orders are expected in both lines. The Clyde, Belfast, and the Tyne together booked more merchant work in the six weeks ended November, 1933, than in the whole twelve months of 1932—and far more naval work too—and it seems probable that 20 per cent. of the building berths will be occupied at the beginning of the New Year, compared with only 5 per cent. fifteen months ago. Still more work is in prospect. Old ship "scrapping" is proceeding at four times the rate it attained in 1932, and the price of scrap is a good deal higher. Much of the money obtained from the shipbreakers will be spent on the new economy ships our builders offer, for owners realise that if they are to remain in business they must have modern ships. Our metallurgists have so improved steel, our engineers have so improved engines, boilers, and auxiliaries, and our shipbuilders have so improved their productive methods and the make and shape and adaptability of ships, that the forty, thirty, twenty, and even in some cases the ten-year old vessel is no longer economical to operate. In fuel consumption alone, per ton of cargo capacity and per knot of speed, the new ships are far more economical than the old vessels. We expect to see old ship "scrapping" on a huge scale, and new ship construction on a large scale. Among other factors there is a movement to reserve coastal and inter-Empire trade for British shipping, as foreign nations reserve their trade for their own ships, and for equalising in other ways the competition between foreign protected and subsidised shipping and our own shipping. Foreign subsidised shipping has eaten seriously into our commerce, but opposition to it augments daily, and we may soon see the percentage of British imports and exports carried in British bottoms increased.

Fortunately, the ability of our shipbuilding industry to meet competition within its own scope stands high. There are no shipyards in the world better equipped or laid out than British yards. Any little decline we suffered a few years ago by comparison with new yards abroad has been made fully good. There are no overseas yards nearly so well placed as our yards are in the matter of supplies of material. Our yards are close by coal mines and steel works. A ton of shipbuilding steel, like a ton of fuel required for a shipyard, carries the lowest transport costs in the world. The transport charges on shipbuilding materials in America, Germany, Holland, and the other competitive countries range from three up to nearly twenty times as much as in Great Britain. We actually have mines, ironworks, and shipyards next door to one another in this country. And we have workmen and engineers with an ingrained—almost an inborn—capacity and skill for ship construction. Given a continuation of industrial peace, and our resources and abilities justify a hope in the resuscitation of shipbuilding before many months have passed.

Literature.

Moscow, 1911–33: *Being the Memoirs of Allan Monkhouse.* London: Victor Gollancz, Ltd. 1933. Price 16s. net.

We need not remind our readers that Mr. Allan Monkhouse is one of those Metro-Vick engineers whose arrest by the Soviet Republic last March caused an international sensation. Reading his memoirs one is more than ever astonished by that event, for by every word he uses Mr. Monkhouse shows himself sympathetic to Russia, the Russian people, and Russian ideals. There is a not unnatural tendency to think, "here is a man who has lived in Russia for many years, who has been expelled from it in disgrace, and is anxious to curry favour so that he may again be taken into favour." No human emotions are single and simple, but we are convinced that Mr. Monkhouse has written from affection and that ulterior motives have weighed little, if at all, with him.

It is a readable book, written in an easy and pleasant style, and covers a long period and a large area. But, as brother engineers with those who suffered the indignity of imprisonment, we turn at once to a chapter entitled "The Moscow Arrests, March 11th, 1933." It opens with these words, of whose significance the meaning later becomes clear: "In January, 1933, it was evident to a great majority of the population of the U.S.S.R. that the first Five-Year Plan had not completely fulfilled expectations." Stalin, on January 7th, 1933, had explained the failure by asserting that opponents "are doing as much mischief as they can, working silently underground. They set fire to warehouses and break machines. They organise sabotage," and so forth. But there were sceptics, and a counter-revolutionary plot had to be "revealed." Accordingly, on March 11th—the day of the arrests—the O.G.P.U. announced the discovery of widespread counter-revolutionary activities. But the trouble began several weeks earlier, when Miss Kutosova, Mr. Monkhouse's private secretary, was suddenly arrested in his office and dragged off by the O.G.P.U. She returned next day a broken woman, with ink-stained fingers, silent on what had happened to her, but evidently forced "under threat of serious consequences to herself and probably to her relatives, to act as an agent of the O.G.P.U." That was on January 25th. Two days later Mr. Monkhouse's suspicions were aroused by other events, and on February 6th, 1933, he came to London. Here he was assured, in the presence of his own Chairman, by Mr. Ozerski, the Soviet Trade Representative in London, that the O.G.P.U. had nothing against the company and nothing against him personally. Acting on that assurance he returned to Moscow on March 7th. Then, four days later, "We had finished dinner, and were seated in the lounge, when suddenly a door was thrown open, and, almost before we could realise that anything unusual was occurring, eight stalwart O.G.P.U. officers and N.C.O.'s were in the room. They were led by a dark young officer of short stature, who, it afterwards transpired, was actually one of the highest officials in the much-dreaded organisation." There followed a search "as thorough as imagination could make it," but rendered grimly ludicrous by the sinister meaning attached to correspondence with the British income tax authorities, and the difficulty of explaining away a small boy's drawing of a "puffer"! In the first hour of the morning the search was complete and Mr. Monkhouse was taken to the Lubianka Headquarters. The rest of the story would take too long to tell, but it is related with dramatic effect. It came as suddenly to an end as it had begun. Two days later the prisoner was released on the condition that he did not attempt to leave Moscow.

The following chapter is devoted to the Moscow Trial. In view of the opinions held by some, and of Mr. Monkhouse's long knowledge of and real sympathy with Russia, his own concluding words must be quoted: "It only remains to be said that the Soviet Government has allowed its responsible agents—the Economic Department of the O.G.P.U., the Public Prosecutor of the R.S.F.S.R., and, finally, Judge Ulrich, of the Supreme Court of the U.S.S.R.—to organise and stage a trial which has been correctly described as a travesty of justice, and which has, without doubt, discredited their Government and their country in the eyes of the civilised world." No contention that the author, as one of the victims and as the intimate friend of others, was biassed and incapable of fair judgment can weaken the force of his assertion, for, as we have said, his sympathies are with Russia, and he is no doubt familiar with the ordinary course of the justice in that land. "As one who has made it his duty," he writes, "to understand the aims, ideals, and objects of the Soviet Government, and has done his utmost to interpret this knowledge of the U.S.S.R. to promote a better understanding between Great Britain and that country, and, moreover, has done everything he reasonably could be expected to do to assist in the fulfilment of the vast plans of the State Planning Department, it is, indeed, a bitter disappointment to see the Soviet Government become a prey to fanaticism and class hatred to such an extent as to allow itself to be led into a blunder of this kind." How great that blunder was will perhaps never be known, or never be revealed, for the mouths of those who could speak of things which Mr. Monkhouse has withheld are sealed.

We have devoted what space we could spare to the most dramatic part of our author's narrative, but we should leave a wrong impression of his memoirs if we let it be believed that they are all tempered and affected by the episodes of last spring. The shadow of those events does not lie over the major portion of the work, in which will be found an interesting account of Russia and her people, with comments upon her efforts to erect an industrial organisation of vast magnitude, and to establish a new constitution.

The Motion of Railway Vehicles on a Curved Line. By C. F. Dendy Marshall, M.A., M. Inst. Loco. E. London: *The Railway Engineer*. 1932. Price 12s. net.

This interesting paper shared jointly with another the George Stephenson Research Prize awarded by the Council of the Institution of Mechanical Engineers in 1930. It was published in various instalments in our contemporary *The Railway Engineer*, in 1930 and 1931, the corresponding pages being subsequently bound together in book form.

Apart from a concise preliminary history of the practical solution of the problem by means of the bogie, pony truck, and radial axle, and suggestions, towards the end, regarding possible improvements in bogies, the paper describes a mathematical investigation of the motion of vehicles on curves, and of the positions taken up by the wheels of a 4-6-0 engine on curves of various radii.

The motion of vehicles on curves is considered in Chapters II. and V. The author assumes that, in theory, friction should be sufficient to resist the centrifugal force, disregarding in this connection the effect of the coning of the tires. A wheel with a coned tire, if rolling freely, would describe a circle about the apex of the cone of which the tire forms a part, and this apex is situated from 30ft. to 70ft. outside the wheel, the actual distance being ten times the diameter of the wheel. Two such wheels mounted on a common axle are constrained, by the resistance of the axle to elongation, to move along parallel lines, and both wheels are subjected either to a constant side slip, or, more probably, to a series of side slips. Even on straight track it cannot be assumed that equal side slip always occurs on each wheel, and it is only the flanges which ensure equality of the sum total of the side slip on each wheel. On curved track, with either a preponderant centrifugal force or superelevation, it is reasonable to suppose that the wheels would move outwards or inwards with extreme sensitiveness, and the behaviour of railway rolling stock confirms this.

The tension produced in the axle must be sufficient to overcome the friction between wheels and rails, and, with continuous side slip occurring, the rails would be thrust inwards. More probably the rails alternately bend inwards as much as play and elasticity will allow, and then spring back when the resistance is sufficient to overcome the friction, and side slip occurs. In the case of flat-bottomed rails spiked down to the sleepers, it is always the outside spikes which are most worn, even on straight track, indicating that, in actual practice, the rails are subjected to lateral pressure from the flanges of the wheels, exceeding, in its effect, that required to overcome the friction between wheels and rails, and extremely difficult to investigate mathematically.

The comprehensive investigation of the position taken up by the wheels of a 4-6-0 engine on curves of various radii, which forms the subject of Chapter IV., is somewhat difficult to follow, and illustrations drawn to distorted scales would have been helpful, especially as there is very little explanatory text. The calculations depend on perfect track alignment and uniformity of gauge, and such small differences in flange play as $\frac{1}{32}$in.

Bearing in mind the unequal wear of flanges, and the difficulty of maintaining such perfection in the track, it is not surprising that the paper provoked discussion as to the practicability of mathematically investigating the complex movements of railway rolling stock. Such criticism does not detract from the valuable investigation so ably carried out by the author, and is, indeed, necessary as a reminder that in making use of the results, due regard must be given to the assumptions on which they are based.

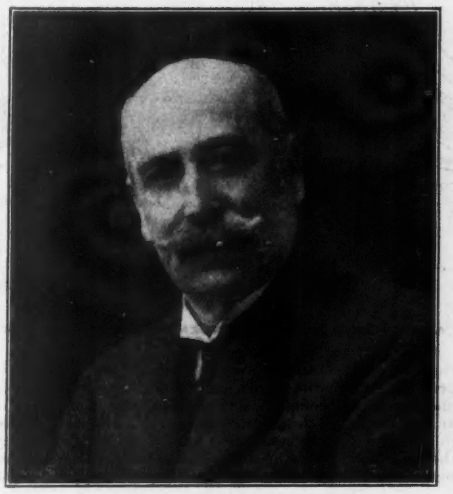
Two formulæ are compared, determining the radii for radial axle-boxes and pony trucks, and attention is drawn to the different results obtained, but as, in the first method, an approximation is used on one side of the equation and an exact value on the other, a precise result cannot be expected.

The Pullman cars that run on various trains of the London, Midland and Scottish Railway in Scotland were, as from December 1st, transferred, with the staff of attendants, from the Pullman Car Company to the L.M.S. Company.

Obituary.

Mr. G. J. CHURCHWARD.

We regret to have to record the sudden death of Mr. G. J. Churchward, until the day of his retirement one of the outstanding personalities of the railway world. His death occurred on Tuesday, December 19th, when, walking outside the grounds of his house on the tracks of the railway company he served so well, he was struck and instantly killed by the "down" Fishguard express at about 10.30 a.m. No one was by to watch his end. Perhaps—who knows?—the man who had devoted his life to the railway would have preferred, had the choice lain in his own hands, just such a quick death as this rather than a long, lingering decline, and a slow failure of all the once alert and active faculties. But to his family and his friends, of which there were many, the shock coming at so unseasonable a time of year was severe. By his own wish he has been buried in the yard of the parish church overlooking on one side the works of which he once had control, and on the other the rolling Wiltshire downs he loved so well.



MR. G. J. CHURCHWARD

From the very first Mr. Churchward's engineering life was connected with railways. Having been born at Stoke Gabriel, in the county of Devon, he started his career as an articled pupil with the South Devon Railway, and when that company was amalgamated with the Great Western in 1876 he was transferred to Swindon. Six years later, with considerable experience in the drawing office behind him, he was appointed assistant manager in the carriage works. Here, in collaboration with Mr. Joseph Armstrong, Junr., he proved of what mettle he was made by perfecting the vacuum brake. Later, directing his attention to the lubrication of carriage stock, he developed a system of resilient pads and oil boxes which has been found so satisfactory and efficient that it is almost universally used to this day. The change of gauge gave him the opportunity to demonstrate his powers as an organiser in distinction to his abilities as a designer, and the novel and efficient arrangements he made in conjunction with Mr. Dean for anticipating the requirements consequent upon the change so far as coaching stock was concerned, are still remembered. During his time many improvements were made in rolling stock. He was concerned in the development of gas and later of electric lighting for coaches, and in the fitting of the vacuum brake to goods stock, to mention but a few of his activities.

But, unquestionably, Mr. Churchward will be best remembered in connection with locomotives. He early realised the value of standardisation, and with this object in view directed his attention to locomotives, and particularly locomotive boilers. No one, least of all the Great Western Railway, is likely to forget his services in this direction, for the four-cylinder, six-coupled engines he designed placed the company in the forefront of locomotive practice in Great Britain. His most celebrated engine, which conformed with the standards he had adopted, was "The Great Bear."

In 1902, on the retirement of Mr. William Dean, the post of chief mechanical engineer was given to Mr. Churchward, who held it with great distinction for nineteen years until his retirement at the end of 1921. During this period the steady march of progress under his direction raised steam pressures from 180 lb. to 225 lb. per square inch, and brought into use the superheater.

Although, to the laymen, Mr. Churchward's name is indissolubly connected with improvements in locomotives, by railwaymen the value of his work in organising maintenance work is fully realised. With the advice and help of subordinates he designed the standard Great Western (1-2-3-4) unit engine shed, of which many have been erected since 1902, and it was during his time as chief mechanical engineer that the value of water softening was realised. Eight plants were brought into use.

But it is not only in his railway work that the effects of Mr. Churchward's beneficent personality are to be traced. His death is a great loss to the inhabitants of Swindon, who had looked to him during many years for support and guidance. In his public capacity he gave his services generously. As early as 1897 he became Chairman of the new Swindon Urban District Council, and he was for many years a member of the Water Board. In the sphere of technical education, in which he took great interest, his zeal and foresight are still remembered by many men now filling posts of authority throughout the world. A few months before his retirement Mr. Churchward was presented with the honorary freedom of the borough. Another honour which he always regarded as a collective acknowledgement of the excellent work performed by the employees at Swindon during the Great War, was his creation as a Commander of the Order of the British Empire.

Letters to the Editor.

(We do not hold ourselves responsible for the opinions of our correspondents.)

STEEL TRADE REORGANISATION.

Sir,—You publish in your issue of December 10th a leading article on "The Steel Trade Reorganisation Plans." It is good to see these proposals given wide publicity, as a scheme such as is laid out by the National Committee is so radical a departure from the system which has formerly enabled this country to lead the world in the steel industry that everyone, even remotely concerned, should give it serious study.

Being intimately connected with one branch of the industry, one may not see all the difficulties of the many other interests equally important and nearly connected. It would appear, however, that the National Committee have been unable to free their minds of a pseudo-socialistic scheme for the industry and wish to eliminate all individualism. This is exceedingly regrettable and, I submit, will never bring progress or prosperity to the British steel trade.

In considering defects in any business one should look to the head, and if faults occur at the top they will surely continue and grow throughout the whole organisation; whereas if there be no failings there, any other troubles will not be very difficult to overcome. Following this procedure, one must consider the case of the actual producers of pig iron and steel in this country, and be sure that if this basic part of the industry were put in order other troubles connected with branches depending on these productions will be remedied naturally and quickly.

There exists at present an association, one of the functions of which has been to fix prices for sale to other manufacturing branches of the trade. These prices have been fixed at levels which allow such a margin of profit that inefficient and out-of-date works can continue to produce and other works seek for ways and means to circumvent their own agreements and in effect sell at a lower price by undertaking part of the work which should be executed by their customers and doing the same at a loss. With such examples of "associations" still continuing to function in this way, surely no other part of the industry will wish to extend the "association" idea.

The basic fact is that the output of the present steel plants of this country cannot be absorbed at the present prices and in the absence of a substantial export trade.

It should be recognised that only the most efficient plants can ultimately exist, and the natural way to attain this object would be to immediately cancel all fixed prices, when a period of healthy and uncontrolled competition would naturally eliminate the obsolete works. Such an action would be quickly followed by similar results in all other branches of the industry and rapidly enable a sound and healthy steel trade to again be built up by individual firms who are anxious to make progress in fair competition with all others.

The legitimate functions of an association could still be exercised in the way of a levy on home trade to assist extension of export business which is eminently necessary to this country or in other internal matters of the industry. No association should be allowed to act in such a way as to prejudice the whole of the industry dependent on its products as the present Steel Association does. Given this freedom and continued support from the Government in the way of import duties to prevent dumping of foreign manufactured products, there is no reason why the industry should not again regain prosperity.

It is unthinkable that the individual firms of this country will submit to control which you rightly term "bureaucratic in inception and construction," and which is utterly alien to the British character and temperament.

Stanley G. Newstead.

London, December 19th.

An interesting example of the use of wireless in industry is the regular communication service maintained by the Consolidated Diamond Mines of South-West Africa, Ltd., between their station at Luderitzbucht (South-West Africa) and their mining camp at Oranjemund, 160 miles distant. The apparatus at each end is worked by a $1\frac{1}{2}$-kW paraffin engine generator set.

The Johnson Naval Type Boiler.

Successful tests have recently been completed at the works of John Samuel White and Co., Ltd., East Cowes, on a "Johnson" marine type water-tube boiler, manufactured by Clarke, Chapman and Co., Ltd., of Gateshead-on-Tyne, for demonstration to the Admiralty. We recently attended full-power and overload trials of this boiler, of which a description is herewith given.

The Gateshead firm, it will be recalled, now holds the British and foreign rights to manufacture and to grant sublicences for the manufacture of this boiler. The first unit of this type incorporating an air heater and superheater was built by John Brown and Co., Ltd., at Clydebank, successful tests being completed in January, 1929. The maximum rate of steam generation was 13 lb. per square foot of heating surface. It was subsequently installed in the Canadian Pacific liner the "Empress of Britain," as one of a battery of nine main boilers, and has been in regular use ever since that ship was commissioned in May, 1931, working at a rating of 10 lb. per square foot of heating surface, or double that of another type of boiler in the same installation.

A smaller boiler, having an air heater, but no superheater, was built by another firm in 1930, and installed in the Canadian Pacific Railway Company's steamer "Princess Helene," in conjunction with two boilers of a well-known design. Prior to the official trials, the "Johnson" boiler was tested up to a rating of 12 lb. per square foot of heating surface, corresponding to 14·7 lb. from and at 212 deg. Fah. It was utilised in conjunction with the other two main boilers throughout the official speed and power trials, on the completion of which the vessel steamed from Greenock to St. John, N.B., at a speed of 14 knots with only the "Johnson" boiler in use for propulsion.

The "Johnson" boilers fitted in these two ships were the outcome of efforts on the part of the designer to produce a water-tube boiler suitable for merchant vessels, and capable of being worked continuously at a rating of at least 10 lb., with high efficiency. The results obtained in the two vessels mentioned have been so satisfactory that, after due investigation by the builders' and owners' representatives, it was decided to adopt this type of boiler for the Royal Mail liners "Asturias" and "Alcantara," in which the space available is unusually restricted for the power required. These boilers are now in an advanced state of construction.

The British Admiralty having exhibited interest in the potentialities of the boiler for naval purposes, a design was prepared and a unit duly constructed for demonstration by Clarke, Chapman and Co., Ltd. The results of the tests on this boiler constitute a notable technical achievement in the sphere of naval boiler performance. The essential data are given below, permission for publication having been granted by Vice-Admiral Brown, Engineer-in-Chief of the Fleet. The boiler, which we illustrate on page 644 and in Figs 1 and 2, has a generating surface of 9020 square feet and superheater surface of 1810 square feet, and was designed for a continuous evaporation of 165,000 lb. per hour. This output was, in fact, maintained during a special test for a period of twenty-four hours. The specified air pressure corresponding to this output was 4in., but with all ten burners on, it was actually 3·8in. An overload test of four hours' duration at a mean evaporation of 192,000 lb. was conducted later, and subsequent examination of the fire tubes and refractory revealed no signs of distress or damage. In both these tests exceedingly good combustion was obtained with standard Admiralty burners. The boiler was not provided with an air heater :

Figs. 1 and 2—Sectional Arrangements of Johnson Boiler

Naval Boiler : Result of Tests.

	Designed load.	Overload.
Actual evaporation	166,320 lb./hour	192,122 lb./hour
Equivalent evaporation (from and at 212 deg. Fah.)	203,500 lb./hour	236,000 lb./hour
Steam pressure	300 lb. sq. in.	300 lb. sq. in.
Steam temperature	627 deg. Fah.	637 deg. Fah.
Feed temperature	183 deg. Fah.	183 deg. Fah.
Total fuel burned	14,069 lb./hour	17,140 lb./hour
CO_2	13·4 per cent.	13·44 per cent.
Funnel temperature	797 deg. Fah.	880 deg. Fah.
Air pressure at fronts	3·8in. W.G.	5·62in. W.G.
Lb. of fuel per burner.. ..	1,407 lb./hour	1,714 lb./hour
Ratios ;		
Evaporation per sq. ft. of generating surface :		
Actual	18·45 lb.	21·3 lb.
From and at 212 deg. Fah.	22·55 lb.	26·2 lb.
Evaporation per unit of boiler weight	1·3	1·5
Fuel burned per sq. ft. of generating surface ..	1·56 lb.	1·9 lb.
Fuel burned per sq. ft. of total heating surface ..	1·3 lb.	1·58 lb.
Fuel burned per cu. ft. of combustion chamber, volume	15·55 lb.	19·0 lb.

In Fig. 3 we illustrate graphically the results obtained over a wide range of loads. The points of interest in these curves are the variations in superheat, and the relationship between the boiler efficiency and the rate of oil burning. In this connection it may be stated that the radiation and unaccounted—for losses were of the order of 3 to 4 per cent., so that there is every reason to anticipate that the efficiencies which would be registered in an actual, relatively air-tight stokehold would be somewhat higher than those recorded in the present tests.

At the high rates of forcing during the foregoing tests, the furnace temperature, which is always difficult to determine with accuracy, was somewhat less than occurs in furnaces having a large area of refractory, and there was a notable absence of priming, whilst the superheat temperature was steady throughout. At fractional loads, it was found possible by adjustment of the dampers to obtain a considerable increase in the degree of superheat. It was demonstrated that no difficulty need be apprehended in the removal and replacement of fire tubes, it being possible to insert them through the furnace openings and place them in position, the flexibility of the tubes simplifying the operation.

The weight of this boiler with hot water is slightly under 57 tons, so that an evaporation of 86 tons per hour corresponds to an output weight ratio of 1·5. With the experience gained as a result of these tests and various experiments made, the designers anticipate that it will be possible to make refinements in design which will

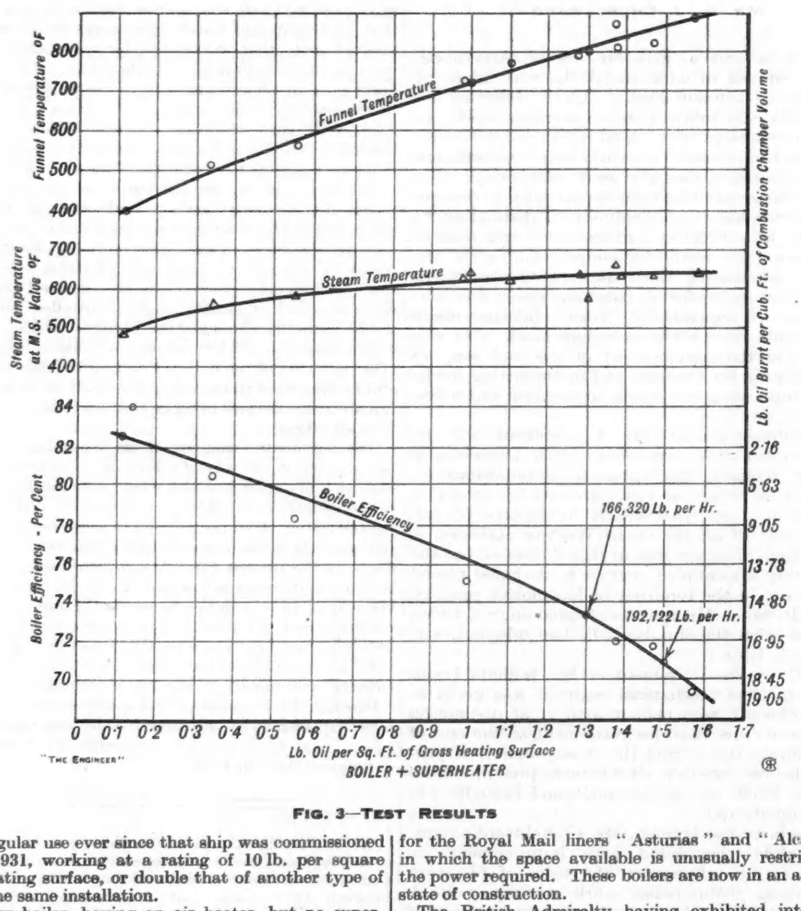

Fig. 3—Test Results

secure an improvement in this ratio. It is interesting to note that the total weight of brickwork in this boiler does not exceed 3·5 tons.

A feature of the test arrangements was the very complete equipment for maintaining the boiler feed and oil fuel supply, and dealing in two large condensers with the large volume of steam generated.

The tests were conducted under conditions arranged to approximate as closely as possible to those obtaining at sea. The boiler was housed in a corrugated iron building in which the atmosphere was kept at 5·63in. W.G. above atmospheric pressure. The air for combustion was not preheated. The feed water was in continuous circulation; after being pumped into the boiler and evaporated it was discharged into the surface condensers and thence to the feed tanks and feed pump suction. The auxiliary plant was as follows:—Two Weir air pumps; two condensers, provided by J. S. White and Co., Ltd.; four fans; two Weir fuel pumps; two turbo feed pumps; one feed heater. The steam was taken from the boiler to a de-superheater, which, in turn, exhausted into the two condensers. The two air pumps then discharged the condensate into calibrated tanks to which the feed pump suction was coupled.

The fuel oil and water were taken from special calibrated tanks which had been tested by the Admiralty. The tests were carried out using instruments approved by the Admiralty, which included a "Mono" gas analyser, a Cambridge multiple temperature indicator, and Budenberg pressure recorders.

Parallel Operation of Single Stage Boiler Feed Pumps.*

By Lieut.-Commander H. J. REDFIELD, U.S.N.

SEVERAL articles appearing in this publication have indicated the numerous advantages of the high-speed, single-stage centrifugal boiler feed pump for naval use. Pumps of this type were specified and obtained for heavy cruisers 24 to 31 having a head-capacity characteristic which was practically flat from the rated capacity (750 gallons per minute) to shut off. Actually, these units showed a slight droop at shut off or zero capacity (see Fig. 2, curve X).

The original idea in using flat characteristic pumps, proposed that by a flat characteristic no pressure-regulating governor would be necessary, since the pump would maintain a constant head at constant speed regardless of the capacity. This idea is perfectly sound, and pumps having a flat characteristic actually demonstrated that no pressure-regulating governors are required where paralleling is not necessary.

FIG. 3—PARALLELING OF PUMPS WITH ONE PRESSURE GOVERNOR

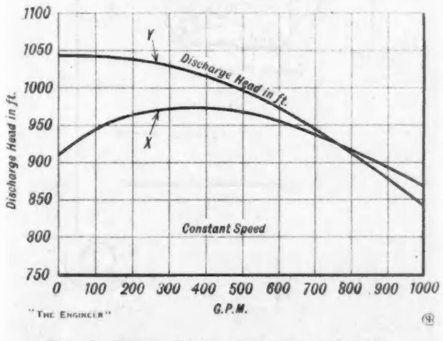

FIG. 2—FEED PUMP CHARACTERISTICS

As soon as parallel operation was attempted, however, these units showed that parallel operation, especially at lower capacities, was extremely unstable, and violent surging of the units and slamming of the check valves occurred. This surging or see-sawing (first one pump taking practically all the load, and the other pump dropping the load, and *vice versâ*), and slamming of checks results from the fact that with two pumps with so-called flat or drooping characteristics discharging into a common main, there are no factors existing in the installation which will influence the pumps to operate on a fixed point of their head capacity curve when the combined output or capacity is constant. It should be remembered that the discharge pressure is the only common controlling factor for two pumps operating in parallel, and with a flat characteristic pump, such as curve X, Fig. 1, it will be noted that for any speed two widely different capacities may be obtained while operating at a fixed discharge pressure.

Thus it will be noted from Fig. 2, curve X, that at constant speed and discharge pressure of 945ft. one pump may operate at a capacity of 100 gallons per minute while the other pump is operating at a capacity of 650 gallons per minute. Now any change in the system such as opening or closing feed checks to boiler will result in a disturbance of these operating conditions. If total feed demand is reduced from the 750 gallons per minute previously delivered, the discharge pressure will tend to rise on the pump previously operating at 650 gallons per minute, and tend to lower on the pump operating at 100 gallons per minute. This will result in the 650 gallons per minute pump hogging all the load and the 100 gallons per minute pump dropping the load with reversal of flow from the pump of higher pressure, and the slamming of the check on the 100 gallons per minute pump. With this pump off the line (operating at shut off) its speed will tend to rise with consequent rise in discharge pressure, and this pump will come back on the line and its higher pressure will cause it to take the load with the other pump previously carrying the load dropping same, due to the fact that when it takes all the load from the other pump its speed and pressure will automatically lower, and it will go off the line with consequent slamming of its discharge check valve.

With few exceptions, the leading manufacturers of this type of unit, both in this country and abroad, held that it was impossible to parallel single-stage pumps, and that they were regarded as "single-purpose" units not suitable for parallel operation. It was contended by one manufacturer that the rising characteristic could only be obtained by a considerable sacrifice in efficiency. These claims, however, have not been substantiated by test, as the rather elaborate tests conducted on pumps of certain manufacture have shown that these rising head characteristic units have higher efficiency than any units of similar type in service.

The manufacturers referred to above, however, stated that they could furnish new impellers for the units they had in service, such that the "flat" characteristic would be changed to a uniformly rising characteristic, and that with the new impellers their pumps would parallel at any capacity.

A uniformly rising head characteristic pump presents no difficulties for parallel operation, because for any given condition at constant speed, there is only one point at which the pump can possibly operate. Curve Y, Fig. 1, shows the rising head-capacity curve obtained by a change in impellers on pumps previously having a flat or drooping characteristic as shown on curve X, Fig. 2.

The Bureau accepted the offer of this company to demonstrate their claims, and the tests conducted fully justified their contentions, and the units concerned paralleled very satisfactorily under all possible operating conditions.

Faced by the established fact that it could be done, other manufacturers have developed modifications, such that all cruisers originally having flat characteristic pumps soon will have pumps with a rising characteristic which will parallel satisfactorily under any capacity condition.

Units essentially similar to those on the earlier cruisers are now being supplied, and it is the purpose of this article to briefly describe the paralleling tests conducted at the Engineering Experiment Station, Annapolis, Maryland, on these units as indicative of the results to be expected from the operation of rising head capacity boiler feed pumps operating in parallel.

The test set up consisted of two No. 5½ Class SFU Buffalo single-stage, double-inlet boiler feed pumps, driven by type BAN Terry turbines. Each pump was fitted with a standard commercial horizontal swing check valve on the discharge and a 3in. Swartout S C excess pressure pump governor.

Fig. 1 shows the diagrammatic arrangement of the test set up using a separate pressure governor for each pump. With this set up satisfactory paralleling is obtained under all conditions. As one pump was cut out by its throttle valve, the other pump would assume the entire load immediately without any marked hunting. When the idling pump was cut in each pump assumed a share of the load immediately without any fluctuation or other difficulties.

To obtain load equalisation, however, it is necessary to have equal excess pressure governor settings. The water actuating lines to the excess pressure governors may be cross-connected for slightly improved load-equalisation characteristics. This set up permits, if desired, running one or more units at full capacity and controlling on another unit.

Fig. 3 shows the diagrammatic arrangement using one excess pressure governor to control two units. Any pumps of similar characteristics will parallel with equal loads at all times with this system of regulation since, in effect, it gives equal steam chest pressures on the turbines and forces the pumps to run at a fixed point on their head capacity curves.

For units located in different compartments this set up would involve too much piping, and if four units were actuated by a single excess pressure governor, the accuracy of regulation at partial loads would probably be poor. The cross-connecting of the pilot valves on Leslie or Foster regulators in effect is identical to one excess pressure governor controlling two or more units, because it assures equal turbine steam chest pressures on both units at all times. This method necessitates load equalisation at all times, and it is impossible to operate one or more units at full capacity and control with one unit where pumps are thus connected.

It was originally intended in connection with this paralleling test to determine the effect of different types of check valves on the paralleling of the pumps. Certain manufacturers stated that the difficulty in paralleling was caused by the check valves. Various types of balanced non-return and cushioned checks were proposed to eliminate the difficulties. However, results of later tests have indicated that the conventional swing check valve is entirely satisfactory with a pump of the correct characteristics, and the drop across this type is about one-tenth the drop across the cushioned vertical lift type. The complications, therefore, of the "balanced" or cushioned type of check valve do not appear to be justified as there is no necessity for other than the simplest type.

Further, with the cushioned checks, in cutting out a pump the check valve will tend to "hang open" until a considerable back flow through the pump being cut out takes place. This results in an appreciable drop in pressure on the discharge main, and when the cushioned check does close a water hammer is set up in the piping. In the case of swing checks no such hang open exists and, consequently, no water hammer results.

An additional test with separate regulators for each pump was conducted with the actuating water for the excess pressure governors taken from the common discharge main beyond the check valves of the two pumps. This resulted in unstable operation, surging of the units, and slamming of the check valves.

It is interesting to note that on three separate tests different observers, among whom was the writer, have observed that apparently the check valve on the pump being cut in on the main line starts to open at about 15 lb. lower pressure than is on the line. The check valves were fitted with an external indicator to show the position of the valve at all times. It seems that if this is a fact, it is caused by the velocity reaction from the pump impinging on the check valve. It, therefore, would seem desirable to locate the check valve as close as possible to the pump diffuser to augment this desirable effect.

It may be concluded that the single-stage, high-speed boiler feed pump having a continuously rising characteristic at constant speed with an increase of approximately 12 per cent. in pressure from rated capacity to shut off (no delivery), will parallel satisfactorily in a set up using conventional swing check valves and connected according to Fig. 1 or Fig. 3.

160 B.H.P. Vis-a-Vis Oil Engine.

THE 160 B.H.P. four-cylinder *vis-à-vis* airless injection oil engine herewith illustrated has recently been designed by Mr. H. V. Senior, of the Brush Electrical Engineering Company, Ltd., Falcon Works, Loughborough, for power stations, industrial work, air compressor driving, and marine auxiliary service, and is the first unit of a series of straight-line engines and air compressor units which are to be built by the firm. The range will eventually comprise, besides single-cylinder units, a number of multiple-cylinder units from 120 up to 520 B.H.P. in output, the smaller engines running at 600 r.p.m. and the larger at 330 r.p.m.

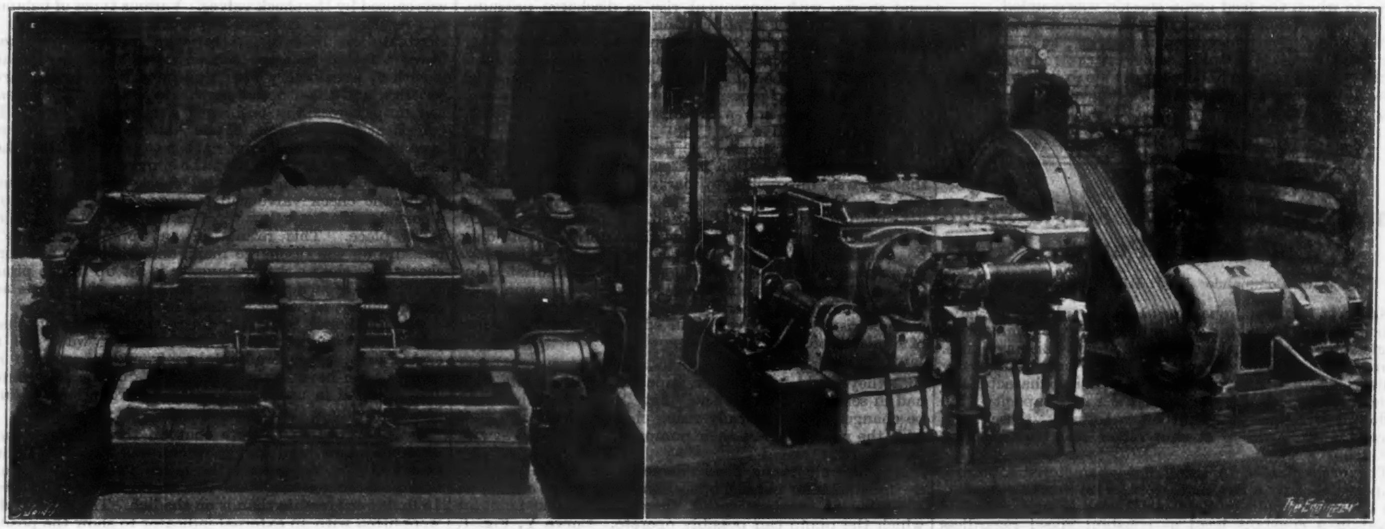

FIG. 1—VIEWS OF 160 B.H.P. 103-kW VIS-A-VIS OIL ENGINE GENERATOR SET

In the engine we illustrate the four cylinders are horizontally opposed, with a stroke of 16½in., giving a designed output of 160 B.H.P. at 440 r.p.m., with a 176 B.H.P. maximum load. As our right-hand illustration above clearly indicates, the engine is belt coupled by means of a Wigglesworth "Texrope" drive to an alternator. It is a Brush, 103-kW, 420-volt machine, which is being supplied to the Downton Electric Light Company, Ltd., and will be run in parallel with an alternator driven by a water turbine. A feature of the set is that when the demand increases the engine and generator speeds can be adjusted to meet the new requirements by fitting appropriate pulleys. During a recent visit to Falcon Works we inspected the engine under test-bed conditions, and noted its general smoothness of running and absence of vibration. We were informed that final fuel consumption figures had not been obtained, owing to adjustments which are being made with the fuel pumps and the sprayer nozzles, but that results of the order of 0·39 lb. of oil per B.H.P. hour under full load conditions are already indicated.

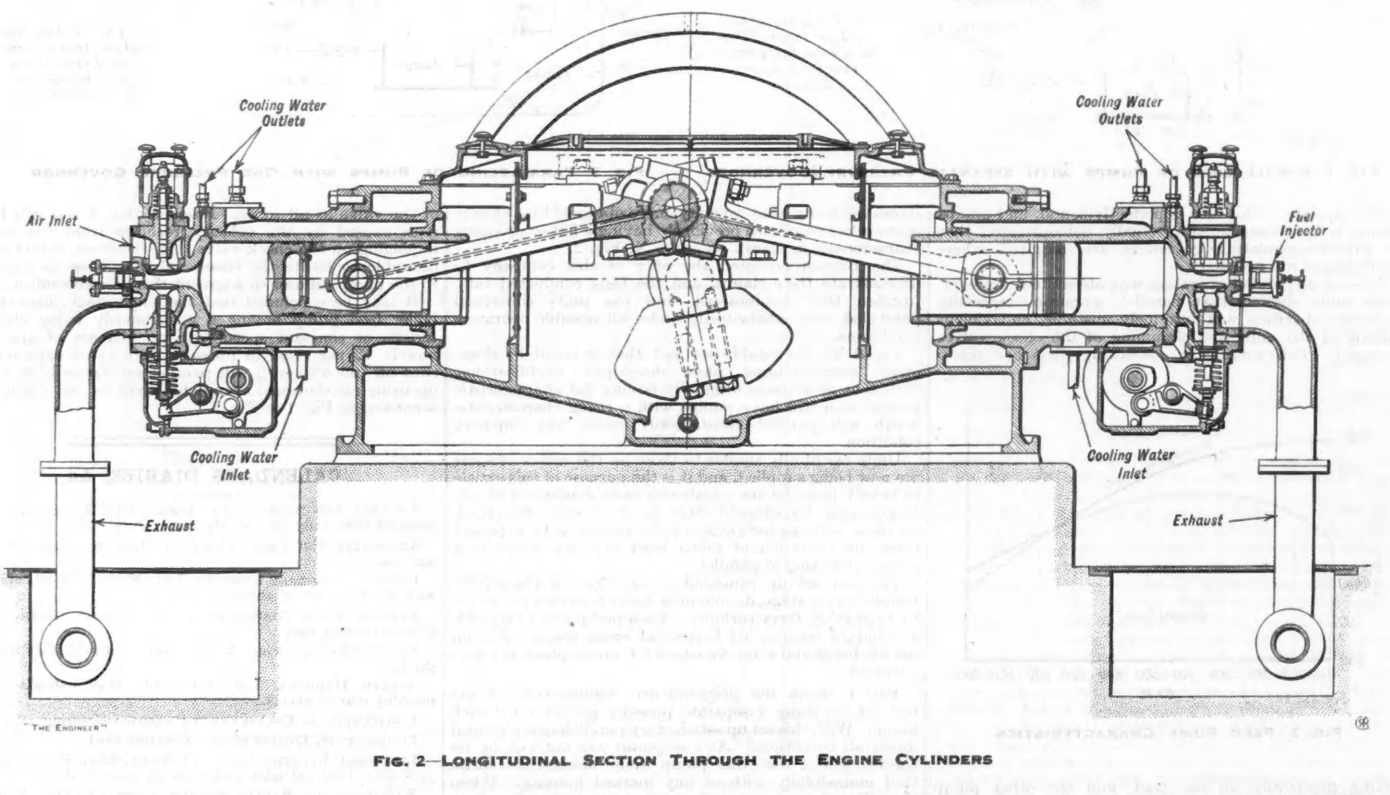

FIG. 2—LONGITUDINAL SECTION THROUGH THE ENGINE CYLINDERS

The outstanding characteristic of the new engine, which is shown clearly in our drawings, Figs. 2 and 3, is the adoption of a compact and completely enclosed bed-plate and crank case, and the enclosure of all working parts. Pressure lubrication at 15 lb. to 20 lb. per square inch is applied to the main crank shaft bearings, and all working parts, only the outboard bearing, which requires less frequent attention, being arranged for oil ring lubrication. Rigidity has been secured by the adoption of a deeper section of bed-plate than usual in normal design, which is reinforced by transverse ribs and is faced on the top to carry a machined oil-tight cover of light construction. On either side of the crank shaft the bed-plate frame is extended in an upward direction, and the horns so formed are tied together by steel bars. The joints of these bars include a special tensioning device, so that the initially tensioned members may ensure greater rigidity and prevent any springing of the bed from taking place The main bearings are each 5¼in. in diameter with a 5¾in. crank pin. The foundation bolts pass right through to the top of the bed-plate, and have concave tops in order to assist in positioning the bed-plate when lowering it into position and to facilitate the easy threading of the nuts. As will be seen from Fig. 2, guarded oil baffle plates are placed within the bed-plate so as to form special oil sumps for the used cylinder lubricating oil, which is thus kept apart from the main lubricating oil supply. The two-throw crank shaft is ground and is made in high-tensile heat-treated steel to the requirements of Lloyd's Register of Shipping specification, and the cranks are fitted with balance weights. Nickel-chrome connecting-rods are used and considerable ingenuity is shown in the special design of large end bearings, which provides a large rubbing surface on the crank pin for both big ends. By removing the top cover complete access is given to all bearings.

The pistons are made of heat-treated aluminium alloy, and are specially long. They carry five pressure rings and one oil scraper ring, while a fully floating type of gudgeon pin is used. Special provision is made for lubricating the pistons completely, but at the same time preventing any lubricating oil from reaching the combustion spaces. The liners are symmetrical castings made in a close-grained nickel cast iron, and are pressed into the cylinder casings and supported by rings forming part of the cylinder casing casting. Both the pressure and water joints are made by the clamping action of the breech ends, and they are visible and easily accessible. The design of the liner and its fastening is such that the forward end is quite free to expand.

We illustrate in Fig. 4 the component parts of one of the breech ends of the cylinder, and a completed cylinder head. The main casting, sections of which are shown in Fig. 2, is of symmetrical design, so as to be free of casting stresses and is made in a cast iron alloy and heat treated. The design is such that there are no ties between the hot walls of the combustion chamber and the cooler walls of the jacket, while the cooling water space is enclosed by a steel breathing plate, which is attached by studs to the fabricated jacket cover. The cover and plate are shown to the right of Fig. 4. The combustion space itself is of a simple symmetrical form, with no dead air pockets, and although the breech end of the cylinder is water cooled, this cooling system is entirely separate from that of the liner, so that a leaky cylinder joint does not allow water to pass to the working cylinder. The cylinders are furnished with relief valves. The cam shafts, which are arranged transversely below the ends of the cylinders, are driven by skew gearing from a central box—see Fig. 5—on the side of the crank case, which serves as a housing for the governor and the lubricating oil pumps and their drives, and also as a support for the fuel pump units and their controls. The cam shaft drives are completely enclosed and are fed from the pressure lubricating system. As Fig. 2 shows, the exhaust valve is directly operated from the cam shaft through an adjustable rocking lever, worked from a hardened steel cam, while the inlet lever is operated by an adjustable short hollow push-rod and lever, which is pressure lubricated, and is accessible by lifting a light cover. The air and exhaust valves are made of alloy steel and the stem of the exhaust valve runs in a long cast iron guide, which is lubricated by a wick feed.

The air starting equipment works in conjunction with a 200 lb. to 300 lb. pressure air receiver, and the air starting valve control gear is connected with the decompression gear which lifts the exhaust valves. The operation is carried out by a single lever, which in its movement passes through the half compression position and gives the initial impulse of air, the further admission being made by the cams. The arrangement of the governor, lubricating oil pump, and fuel pump drives is shown in Figs. 3 and 5. The vertical spindle oil pump is of the gear wheel type, and submerged within the oil tank; it is driven by skew gear from the end of the crank shaft and an extension with an upward gear drive also serves the tachometer and the governor. The oil for the pump passes through an Autoklean filter, and thence to the main oil supply pipe within the bed-plate, which supplies the main bearings and running parts. The pressure within the lubricating system can be controlled by an adjustable relief valve.

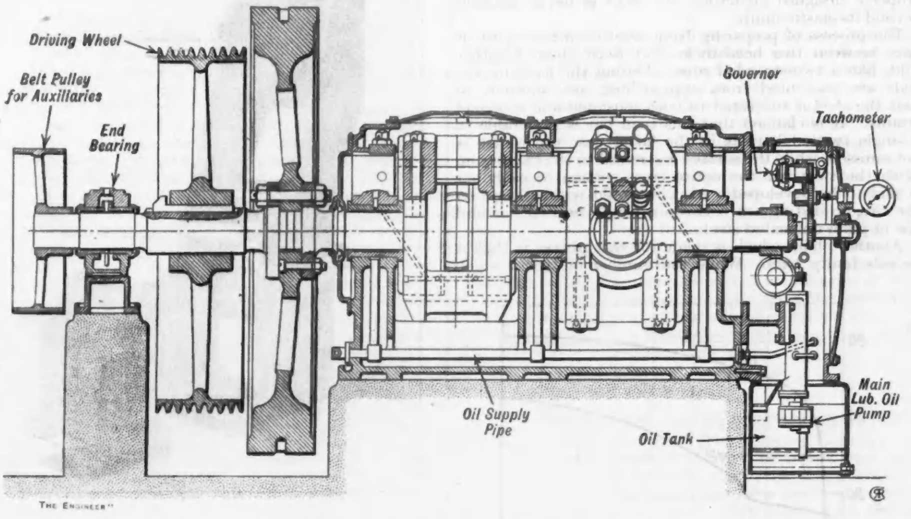

FIG. 3.—CROSS SECTION THROUGH CRANKSHAFT

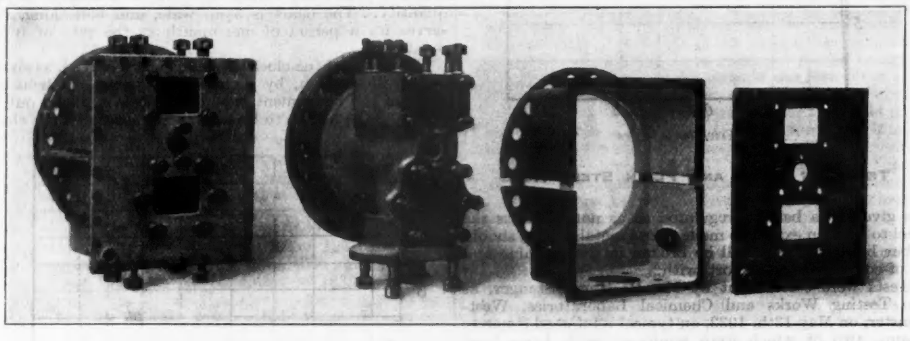

FIG. 4—BREECH END OF CYLINDER WITH FABRICATED STEEL COVER

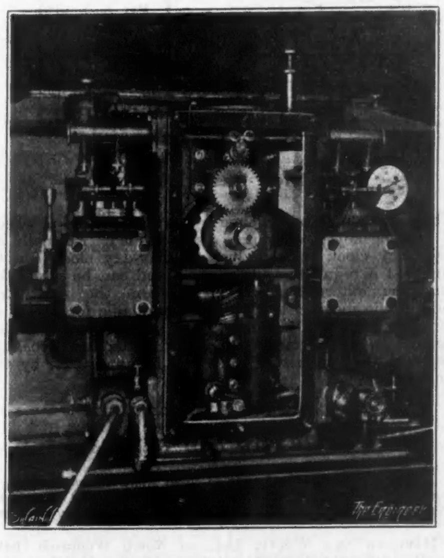

FIG. 5—FUEL PUMPS, AND GOVERNOR

Fig. 5 shows the fuel pump arrangement, which consists of four standard flange pattern Bosch pumps with standard injectors. The fuel pump cams are enclosed within a box with an easily removable inspection cover, and means are provided for putting out of action any one, or more than one, of the four pump units. Each pump has a hand priming lever, which is released by a spring-loaded catch, and the injection period can be varied by a single lever at the side of the pump, which moves over a notched rack. This arrangement permits of a wide choice of fuels being used with appropriate fuel pump settings. The lubricating oil system is also provided with a hand-operated priming pump and spray orifice lubrication for the gear wheels shown in Fig. 5.

The engine we have described was opened up for inspection after a full load run and all the bearings were quite cool. A feature of the design is the enclosure of all parts in casings with removable covers of small size, so that the engine can be conveniently dismantled and re-erected in a small space. Further performance trials are to be made, particulars of which we hope to publish in a later issue.

Some Engineering Works in Czechoslovakia.

MUCH information of interest to British engineers was given by Mr. T. Makemson, the General Secretary of the Institute of British Foundrymen, in a paper which he read, on October 4th, at a meeting of the London branch of that body. He has returned recently from the International Foundry Congress at Prague, which was arranged by the Czechoslovakian Foundrymen's Association, and was attended by some fifteen foreign delegations, of which the British was the largest; and in his paper he gave some of his impressions of foundries, blast-furnaces, and steel works which he visited in Czechoslovakia, during the comparatively short time available to him.

In the first place, he drew attention to the difficulties which that new country experienced immediately after the war, owing to the delimitation of frontiers, the shrinking of the demand for war material, and the comparatively restricted home market. The people had adapted themselves, however, with amazing energy and ability, and their success in the export trade had made them formidable competitors to every manufacturing country in the world. The peak year of the country's prosperity was about 1929; since then the general world conditions, tariffs, and the condition of the exchanges have made the export position more difficult, so that to-day many of the plants are working at considerably less than full capacity.

The first works to which Mr. Makemson referred in his paper were those of the Ceskomoravska-Kolben-Danek, Ltd., at Prague. The company was formed by a merger of three other companies, and its manufactures include steam turbines, generators, transformers, electric motors, water turbines, locomotives, domestic pumps, and brewing machinery.

In a reference to the malleable iron-foundry there, and the annealing of malleable castings in a large gas-fired furnace charged through the roof, which is in sections, he mentioned that cast steel annealing boxes of about 2ft. diameter and 3ft. depth are used, and 0·5 per cent. copper is added to the steel used for making them. It is claimed that their life is prolonged thereby.

A special section of the non-ferrous foundry is devoted to the making of castings in Electron metal, a magnesium and copper alloy with a specific gravity of 1·2 and a melting point of 520 deg. Cent. Crank cases and other automobile castings, commonly made in aluminium, are being manufactured in this metal. It is the experience at these works that a casting temperature of just over 600 deg. Cent. gives the best results. The metal is melted in iron pots and poured into the casting ladles, which are allowed to stand, each pot with a pyrometer inserted, until the metal has cooled to the correct casting temperature. The method of running the moulds is also important. The vertical down runners consist of cores, each core forming three, or, in some cases, four narrow down gates. Horizontal gates carry the metal to each side of the mould, and the ingate is almost continuous. Chills and denseners are employed extensively. Where high corrosion resistance is required, castings of this metal are dipped in a solution of potassium bichromate to increase their resistance, and they then attain a bright golden colour.

Two of the four bays of the iron-foundry are devoted to heavy work in dry sand and loam, and the moulding practice appears to be similar to our own. For smaller work on a repetition basis there is a number of moulding machines, practically all of the press turn-over type, and in this section of the foundry there are gratings in the floor with underground conveyors for the return of used sand.

The pattern shop is a magnificent building on the ground floor, containing an abundance of machines of modern type, and in good condition. Timber is stored in the basement, and the stores are equipped with a very complete timber-drying plant, consisting of three kilns and the necessary steam-raising and air-heating plant. Planks of unseasoned timber are loaded into a truck which is run into the kiln, and there saturated with steam for five hours, by which time the steam is considered to have driven out the natural sap. By an arrangement of valves, the same steam is then used to heat air which is circulated through the kiln for approximately seven days at a temperature of 50 deg. Cent., and dries out the moisture with which the timber has been saturated. The boiler plant supplying the steam adjoins the kilns, the fuel consisting almost entirely of shavings, waste timber, and other rubbish from the pattern shop. This is an extremely fine plant, and though much of the dry timber was warped, there did not appear to be any considerable cracking, and it was claimed that the warping did not cause trouble.

The general impression of this works was that the equipment is good, but not particularly novel; but the work, as a whole, is of the highest quality. The company is obliged to endeavour to create a large export market, and it is essential that the plant be sufficiently flexible to cover a very large variety of work. It is difficult to specialise to a considerable extent; therefore, the policy is to have good plant, but not highly specialised.

Another works visited was that of the Vitkovice Mining, Steel and Ironworks Corporation, at Vitkovice, a town adjoining Maraska-Ostrava, in the most extensive coal-field in the country. The company manufactures pig iron, steel and iron and steel castings; it has an extensive constructional and general engineering business, and operates collieries, coke ovens, ore mines, and a refractory-manufacturing plant. The iron and steel works alone cover an area of 10 square kilometres.

There are two blast-furnace plants, one with three furnaces, and another, nearly a mile away, with two furnaces, the two plants being connected by a gas main 1¼ kiloms. long and 9ft. in diameter, and a blast main of the same length, 5ft. in diameter. Also, there are 2½ kiloms. of gas mains to convey blast-furnace gas to various points in the works. There is an extremely ingenious electrolytic gas-cleaning plant, claimed to be the first of its type in the world.

There are two open-hearth steel-making plants, well laid out and splendidly equipped, and the rolling mills are of very up-to-date design and lay-out. The latter consist of a roughing mill, an armour-plate mill, three other mills for plates and sheets, and mills for rails, sections for structural work, and various mills for strips and rods. There is also a tube mill. The equipment is designed for quick rolling to avoid re-heating as far as possible, and in a test the time taken from weighing the ingot before entering the roughing mill to the finished product about 100 mm. square in section was 5 min. 2 sec. The rolling mill equipment is electrically driven, and Mr. Makemson described it as a wonderful display of modern engineering.

After a brief reference to the ironfoundry (which is said to be the largest in Czechoslovakia), and the machine shops, erecting and constructional shops, and the forges, Mr. Makemson drew attention to the considerable economies which have been effected in the consumption of fuel by the Vitkovice Company. In 1929 the entire consumption of fuel, including coal and gas, per ton of ingots produced, was 45·7 per cent. of the consumption in 1920. This result was accounted for partly by the larger output, which, in 1929, was nearly double that of 1920, but it was due mainly to reorganisation directed to the utilisation of surplus energy. Blast-furnace gas is stored in a gas-holder of 50,000 cubic feet capacity, and coke-oven gas in a smaller holder. Blast-furnace gas is used for heating the coke ovens, and the coke-oven gas is consumed in the open-hearth furnaces. Blast-furnace gas is used in the blowing engines and for driving ten large double-cylinder gas engine sets for the generation of electric current. The distribution of the blast-furnace gas is: To blast-furnace stoves, 27 per cent.; boilers, 1·2 per cent.; blowing engines, 10·7 per cent.; electric current generators, 24·8 per cent.; coke ovens, 10·8 per cent.; open-hearth plants, 7·7 per cent.; miscellaneous purposes and losses, 17·8 per cent. The coke-oven gas is distributed to the open-hearth plants to the extent of 56·7 per cent.; rolling mill, 14·5 per cent.; tube mill, 13·2 per cent., and miscellaneous, 15·6 per cent. Additionally, 420 tons of coal are burned daily in gas producers when the works are in full operation, the producer gas being used for the open-hearth plants and the rolling mill. Waste heat boilers are employed extensively for steam raising; the temperature of the cooling water in the gas engines can be raised above the usual temperature without detriment to the engines, and the hot water from the gas engines is used for heating purposes in the works and the works hospital.

Another establishment visited was, of course, the Skoda Works at Pilsen, which, until the end of the war, was one of the principal sources of supply of armaments to the Austrian Empire, and is now, perhaps, the most impressive engineering factory in Czechoslovakia. In view of the necessity for finding different employment for this huge factory after the war there were considerable alterations in the structure of the company, and other industrial undertakings were absorbed. In 1929 the company had nearly 40,000 employees. The range of the company's productions includes metallurgical products, general engineering (which includes prime movers, steam boilers, various types of engines, aeroplanes, river craft and machinery for special purposes), electrical engineering, war material, and mining products.

In a reference to the steel foundry, Mr. Makemson drew particular attention to the section devoted to small castings. Here moulds are made on press turn-over machines and sand is supplied by an overhead conveyor with a hopper and chute over each machine. Each moulder in this section is provided with a short roller gravity conveyor alongside his moulding floor to assist in putting down the moulds. Steel snap flasks are used extensively, and most of the moulds are of skin-dried green sand. Risers are cut off by oxy-acetylene torches and also by saws.

The ironfoundry, one of the largest engineering foundries on the Continent, Mr. Makemson described as an enormous well-lighted, clean and well-arranged building with plenty of room and an abundance of handling equipment. The melting plant consists of six cupolas, varying from 24in. to 64in. internal diameter, and one 4-ton electric furnace, which is used in connection with a duplex process for melting an abrasion-resisting iron for motor car cylinders. This metal is said to contain about 1·8 per cent. silicon and 0·3 per cent. titanium. An acid-resisting alloy containing 16 per cent. silicon and a small quantity of titanium is also manufactured. Both alloys are patented.

Moulding machines are employed extensively in this foundry also, but although numerous fairly light castings are made in considerable quantity, there is little approach to so-called mechanisation. The core-making department is magnificently equipped with handling equipment, stoves, and benches. Oil sand cores are used almost exclusively for the lighter castings; and Mr. Makemson mentioned some oil pump castings where chills were inserted in the cores to prevent porosity at vital points. In one case the chill was embedded in the sand, so that there was a layer of sand between the chill and the casting. A section of this foundry is devoted to the training of apprentices on ordinary production jobs, selected according to their capabilities.

In the non-ferrous foundry die casting is carried out in a pressure die casting machine, where the metal is melted, but is never allowed to become thoroughly liquid, and it is poured into the machine in a pasty condition by a hand ladle. The dies are then subjected to a pressure of from 180 to 200 atmospheres. The output of the machine is said to be 800 small castings per hour. The advantages claimed for this method are soundness, longer life, more accurate finish, and a saving in runners.

All runners, risers, brackets, &c., in the Skoda foundries are standardised. Before any pattern is sent into the foundry it is examined by specialists, the position of runners, risers, &c., marked upon it, and the standards to be used are specified. It is claimed that considerable saving in defective castings is effected thereby, and the lessons learned from defects can be made use of subsequently in an easy and systematic manner. The general tendency in the steel foundry in particular appeared to be in the direction of using a large number of smaller risers, as against a smaller number of large ones.

The pattern stores, a building of about eight storeys, said Mr. Makemson, is most amazing. Each set of patterns is carefully placed in a rack with a space between every two sets of patterns to prevent confusion. It is claimed that the expenditure of so much capital on this equipment is justified, in that the cost of repairing patterns and making good lost pieces before returning to the foundry has been almost entirely eliminated. There is a timber drying plant in these works also.

A well-equipped school for the technical instruction of apprentices is in operation. Foundry workers appear to receive instruction, not only in practical matters, such as gating and rising, but in reasonably advanced metallurgical subjects. Practical instruction in the making of large moulds is given with the aid of wood and plaster models of the moulds and cores. Instruction in safety-first methods is also given.

In a general reference to costs of production, he said it was difficult to compare those applying in Czechoslovakia with those applying in this country, owing to variations of the exchanges and the different conditions. It appeared, however, that wages in Czechoslovakia are similar to or even slightly higher than those paid in this country, at the present rate of exchange, and on the whole there does not seem much difference in the cost of raw materials. Moulding sand, however, can be obtained very cheaply there; there are excellent deposits of natural sand within easy access of the industrial centres, and the cost of sand delivered to the foundry works out at about 5s. or 6s. per ton.

Isteg Steel.

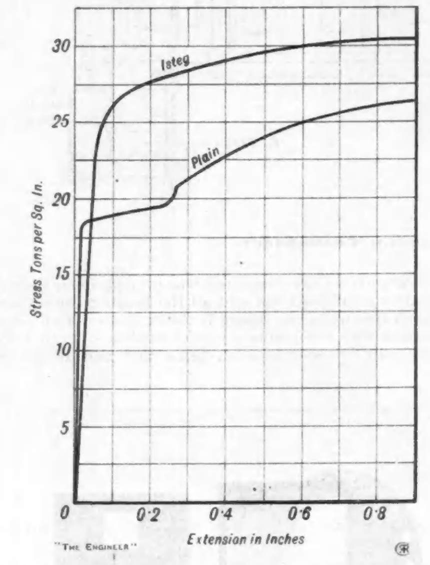
The steel which is used for the reinforcement of concrete works under rather different conditions to that of most other structures, as being associated with a practically inelastic material, it is essential that it should not extend under working loads; otherwise permanent cracks would be produced in the concrete of any member subject to tension, and the opportunity for corrosion provided. For this reason it is usual to employ steel of a high elastic limit for concrete reinforcement, and specifications are sometimes rather severe in this direction.

Isteg Steel Products, of 40, Broadway, Westminster, have, however, discovered a means whereby ordinary mild steel may, they claim, be used to equal advantage as "hard" steel.

The idea, which has found application on the Continent for some years past, is to pre-stress the mild steel, before it is put in place, to such an extent, that its elastic limit is passed. The metal is then allowed to rest before being put in service. The result is that a considerably higher load can be supported before the new elastic limit is passed. We reproduce a graph, which shows how a steel, having a very definite elastic limit of about 17 tons per square inch, may be so improved by the Isteg process that its elastic limit is only approached at about 25 tons per square inch. The test pieces in this case had a gauge length of 24in. It is said, also, that the ultimate strength of the bar is slightly increased, but this is, of course, of no great import in reinforced concrete work, as, in a properly designed structure, the steel is never stressed beyond its elastic limit.

The process of preparing Isteg steel is to fix a pair of bars between two headstocks and twist them together cold, like a two-stranded rope. During the twisting the ends are prevented from approaching one another, so that the steel is subjected to both tensional and torsional strains. It is claimed that this twin bar is preferable to a single twisted bar, as in the latter case the centre is not stressed, while the surface is stressed to the maximum. With the twin bar the entire cross section of each bar is said to be developed. Also, it would not be easy, on the site, to distinguish between a single twisted bar and one of plain untreated steel.

Another claim which is made for the process is that it reveals faulty bars. While the number of twists which are given to a bar are regulated so as not to stress the steel to such an extent to make sound metal brittle, should a bar be defective it will be broken in the machine and is, of course, discarded forthwith.



TESTS OF ISTEG AND PLAIN STEEL RODS

Tests were carried out by Mr. R. Harry Stanger, at the Testing Works and Chemical Laboratories, Westminster, on May 13th, 1933, on typical reinforced concrete beams, two of which were reinforced with Isteg bars, and the other two with ordinary bars. In each case the steel was ordinary commercial quality bar, supplied by Dorman, Long and Co., Ltd., and both sets of bars were from the same cast. The beams reinforced with ordinary bars had 58 per cent. more reinforcement than the beams with Isteg bars, and yet the Isteg beam stood the same load and gave an average stress of 70,000 lb. per square inch for the Isteg bars.

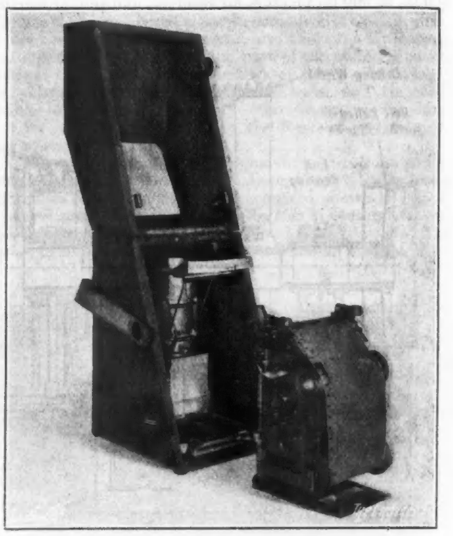
It is of interest to note that tests carried out at the University of Prague eighteen months ago, using similar beams with the same concrete section, reinforced with Isteg bars of Czecho-Slovakian open-hearth steel, gave stresses of 68,000 lb. per square inch.

A Recording Insulation Tester.

When drying out parts of electrical machines and apparatus, such as armatures, field coils, and transformer coils, a knowledge of the insulation resistance during the process is of considerable importance. Frequently, these parts are dried in a vacuum oven, and observation and periodic tests of the insulation resistance have hitherto presented difficulty, but the Evershed and Vignoles recording Megger insulation tester, shown in the accompanying illustration, enables the process of drying out to be observed, and to be permanently recorded. The curve has been reproduced from a chart made by a recording Megger insulation tester during the process of drying out a set of field coils for a small motor, and it clearly shows how the insulation resistance increased with time. When the coils were placed in the oven the insulation resistance was in the neighbourhood of 1000 ohms, and, as the curve indicates, it rose to 36 megohms in the course of 2½ hours, and finally to 40 megohms. The exact time necessary for drying out any particular piece of apparatus can readily be established, and with this knowledge work can be passed through the drying plant in the minimum period consistent with satisfactory drying.

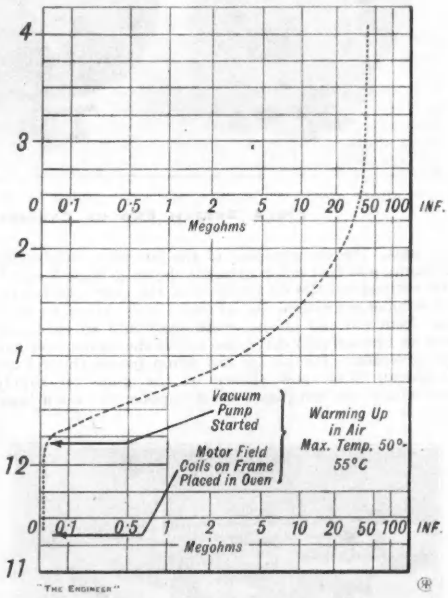
When measuring high resistance, the amount of current flowing through the instrument is very small. It has therefore been necessary to develop a sensitive type of recorder. A tapping or typewriter system of marking or recording has been adopted, so that no load is imposed upon the instrument movement, and a high degree of sensitivity and accuracy is obtained. As the instrument is a moving coil ohmmeter, the readings are independent of voltage variations. Instruments are available for 100, 250, 500, and 1000 D.C., with various megohm scales up to 1000 in the case of the 1000-volt instrument. For operating the instrument D.C. at the testing pressure is required. The amount of current does not, however, exceed 12 milliampères at the lowest reading, and in some cases it is found convenient to employ a well-insulated battery or to work from A.C. mains through a transformer and rectifier. If there is considerable electrostatic capacity in the object under test, special means must be taken to ensure a steady voltage.

The illustration shows the instrument with the clock and recorder removed. On opening the case the supply is automatically interrupted, so that there is no risk of the operator receiving a shock. When the recorder is in use the pointer is depressed by a sharp tap at intervals of one minute on to a typewriter ribbon, thus producing a dot on the chart, which usually travels at the rate of 1in. per hour. Consequently there are sixty dots to the inch, giving a practically continuous line for a slowly varying quantity. The chart is 3½in. wide, and 65ft. long, and serves for a period of one month at the rate of travel mentioned.



RECORDING INSULATION TESTER

The whole of the clock mechanism is removed, as shown in the illustration, by depressing a spring catch at the front of the instrument, when the clock is pulled out by means of the handle to be seen at the bottom of the clock. The chart can be set to time by turning a knurled wheel. A winding key is, of course, also provided. Normally an eight-day clock is used, but a thirty-day clock can be supplied if required. The chart speed can be varied by changing external driving wheels on the right-hand side of the recorder. Wheels are available for speeds of ¼in., ½in., and 1in. per hour. The instrument is guarded against its own surface leakage, and errors due to leakage between the connecting leads can be eliminated by the guard terminal.



INSULATION RESISTANCE CURVE

CONTRACTS AND ORDERS.

The Editor is always happy to print short announcements of contracts and orders in this column provided they are sent to him in time to have news value and that they are likely to interest readers.

Harland and Wolff, Ltd., of North Woolwich, have received from the Associated Portland Cement Manufacturers, Ltd., an order for a small tug, which is to be fitted with a 60 B.H.P. British Kromhout marine oil engine.

PERSONAL AND BUSINESS ANNOUNCEMENTS.

Alfred Herbert, Ltd., have purchased the entire business and plant of the Vidal Engineering Company, Ltd., Thornton-road, West Croydon. It is equipped for the production of electric drills, grinders, polishers, fractional horse-power motors, bench lathes, suds pumps, &c.

Markets, Notes and News.

The prices quoted herein relate to bulk quantities. Unless otherwise specified home trade quotations are delivered f.o.t. Export quotations are f.o.b. steamer. A comprehensive list of the prices of materials mentioned below will be found on the next page.

The Continental Steel Trade.

In no department of the iron and steel market have conditions changed more during 1933 than in the Continental steel department. At the beginning of the year the reconstructed Cartel had only commenced to function, and plans were barely outlined for the international sales organisations which later in the year became effective. Notwithstanding the opposition with which the markets met the selling comptoirs, these organisations appear to have established their positions for the time being, although there is still a certain amount of work to be done in this direction. The latest move of the Cartel has been to set up in the British market pools for the sale of joists, bars, and plates, composed of one representative of each of the existing Continental selling organisations in this country. The British merchants in future will have to buy from these pools, which will sell at the official works prices. So far, no alteration in the Continental steel quotations has followed this arrangement, which, in fact, is hardly yet in working order. It is interesting to compare the prices existing at the beginning of this year with those which now rule. Merchant bars were then quoted at £2 7s. gold or £3 8s. 6d. paper; joists at £2 2s. gold or £3 1s. paper, which was only 1s. higher than sheet bars at £2 1s. gold and £2 19s. 6d. paper. Plates, $\frac{3}{16}$in. and $\frac{1}{4}$in., were quoted down to £2 15s. gold or £4 paper. On the Continent it was asserted that these extraordinarily low prices would have continued to rule had it not been for the resistance offered by the international sales organisation, and it is possible that there is some truth in this view. The quotations at the end of December were:—Merchant bars, £2 15s. to £3 gold, £4 2s. 6d. to £4 10s. paper; joists, £2 16s. 6d. to £2 19s. gold, £4 4s. 9d. to £4 8s. 6d. paper; and sheet bars, £2 8s. gold, £3 12s. paper. Plates, $\frac{1}{4}$in., were quoted at £3 10s. gold and £5 5s. paper for the British market, and £3 18s. 6d. gold and £5 18s. 6d. paper for other markets; whilst $\frac{3}{16}$in. were quoted at the same price for the British market and £4 1s. gold or £6 1s. 6d. paper for other markets.

Pig Iron.

The change in the position of the iron and steel industries is nowhere more apparent than in the pig iron department. At the end of 1932 there were sixty furnaces in blast, whilst at the end of last November, which is the latest date for which official figures are available, seventy-nine furnaces were operating in this country. Production last year averaged 297,800 tons per month, whilst for the first eleven months of 1933 the average monthly output was 309,700 tons. The situation on the North-East Coast at the beginning of 1933 was unsatisfactory, as it was known that the producers were carrying heavy stocks. The suggestion that the pig iron warrant market on the London Metal Exchange, which had ceased to exist since the early days of the war, should be reopened to relieve the situation, was being discussed. In order to obtain business, cheap prices were quoted in Scotland, orders having been accepted at less than 50s. f.o.b. Middlesbrough. The quotations for Cleveland No. 3 foundry were 58s. 6d. for home and export, but less was taken for export if a fair order was in prospect. To-day the position is that all the stocks have been either dispersed or sold and the current production is not sufficient to meet the requirements of the market. So tight is the position that within the last week users have had to bring Midland iron into the district, whilst the producers are contemplating lighting up fresh furnaces so soon as supplies of blast-furnace coke can be assured. Prices also have increased to 62s. 6d. for No. 3 foundry for home delivery, and under the prevailing conditions export business has little attraction for the makers. For Scotland the minimum prices are 65s. 3d., d/d Glasgow, and 62s. 3d., d/d Falkirk. The best that could be said of the Midland pig iron market a year ago was that orders showed a tendency to expand, but not to a sufficient extent to make an impression upon the heavy stocks in makers' hands. It is true there have been no changes in prices for Midland iron, but the position has greatly improved through the reduction of the stocks which are now comparatively small, and the makers are entering the New Year with well-filled order books. In Scotland at the end of 1932 only two furnaces were in blast against ten at the present time. The price of Scottish iron, however, is about 2s. 6d. lower than at the beginning of last year. The change has been scarcely less remarkable in the case of hematite. Most of the stocks in the makers' hands are sold forward, and the current make is so well taken up that it is anticipated that production will have to be increased early in the New Year. Prices have advanced from 59s. at the end of 1932 to 63s. for No. 1 and 62s. 6d. for mixed numbers.

Semi-finished Steel.

The most notable features of the semi-finished steel market have been the tightening in supplies, the advance in prices, and the establishment by the Continental Cartel of a selling organisation for the London market which deprived the British merchants of any share in sale of foreign semis. The quotations at the beginning of the year were for British billets £4 17s. 6d.; to-day the quotation is £5 10s. The price for Continental billets in January, 1933, was £2 18s. to £2 19s. 6d. paper, whilst now it is approximately the same as that for British material. The business now being transacted consists chiefly of odd parcels. Consumers, however, are exercising considerable pressure upon the producing works and in some cases complaints are heard of the latter being late with deliveries. Practically all the producing works are so well off for orders that they can quote only for extended delivery, and on the North-East Coast the earliest date mentioned is February. Premiums are now being asked on forward business, and practically all works quote £5 10s. and some ask 2s. 6d. more for billets. The call for sheet bars is not so insistent and the makers are able to offer near delivery. Prices also remain unaltered at £5 to £5 5s. The tightness in the position has been accentuated by the withdrawal of some Continental works from the market. The quantities of foreign material now being offered are comparatively limited. The quotation for Continental billets varies according to the district from £5 to £5 10s. and for sheet bars it is about £5; but these prices, which include freight and import duty, cannot be satisfactory to the foreign makers. Most of the Continental material which has been offered recently has been billets of German origin, and has consisted chiefly of large sizes. The recent increase in the price of British hard steel billets has had no effect upon the demand, and makers are finding specifications against contracts coming freely to hand. It is noticeable of late that there has been a more active request for acid billets.

Scotland and Lancashire.

The Scottish steel trade at the end of 1932 was in a depressed condition. The shipping industry, upon which the steel trade is greatly dependent, had seldom been so badly off for orders, and in the first month of the year only one contract, and that for a small cargo steamer, was placed with Clyde yards. Little new work had been arranged which was likely to give employment to the construcional engineers, whilst the works dependent upon the railways had few orders on their books to carry over into the New Year. The re-rollers were complaining of the scarcity of business and of keen competition. Conditions, however, steadily improved during 1933, and the industry can look back upon a year's steady progress. The recent orders given out by the railways for locomotives and wagons, the partial revival of the shipbuilding industry, and the orders for engineering contracts which have been placed recently, will enable the Scottish steel works to enter 1934 in a better position than for many years past. For the time being many of the steel works have not yet received specifications as a result of recent orders, but they are assured of this business in the New Year and, in addition, there is a confident anticipation that work will be resumed on the Cunarder, which later on should provide orders for sheets and some of the lighter descriptions of steel needed for ship construction. Featureless conditions marked the opening of 1933 in the Lancashire market. Most of the consuming industries in the district were short of orders, and this was reflected in a poor demand for steel materials. There was a noticeable lack of orders from the constructional engineers, and so far as could be seen little prospect of any increase in activity. Small steel bars were quoted at £6 15s., whilst Continental joists were being offered at £5 5s. d/d compared with £8 7s. 6d. for British joists. At the end of the year most branches of the Lancashire industry are busy and the lighter ones, particularly the re-rollers, are well sold forward. The price of small steel bars has increased to £7 5s. to £7 10s. and competition from the Continent has practically ceased. The structural engineers, although they are not so well employed as a few weeks ago, are entering 1934 with really excellent prospects.

The North-East Coast and Yorkshire.

In no district in the country has the improvement which has taken place during 1933 been more noticeable than on the North-East Coast. A year ago the volume of work in hand was, to say the least of it, disappointing, and although it was said that the prospects for 1933 were promising, it was not expected that any notable change would take place until well into the second quarter. The steel works, however, were just beginning to feel the effects of the tariff upon semi-finished steel and the production of this class of material was being increased. Constructional engineering shops were poorly provided with work. During the year the situation has been radically altered and so strong is the demand for billets and sheet bars that the producers are booked up until February, and in the closing weeks of the year fresh steel furnaces had to be put into operation to maintain the supply. The constructional engineering shops are busy and are carrying good orders into the New Year. The same applies to the railway departments and most of the other sections of the trade, excepting perhaps the sheet works. Even the shipbuilding industry, which has suffered acutely from the depression, shows signs of improving and fresh orders are expected to materialise in January. In Yorkshire the situation at the end of 1932 was viewed with a restrained optimism rather than with confidence. Complaints were general of price cutting to obtain orders for basic billets, and the most that could be said of that department was that the rate of production was fairly well maintained. The works catering for the railways were only moderately busy and disappointment was felt at the failure of the demand for alloy steel sheets to develop. The heavy engineering industries also had a great deal of their plant lying idle. The situation began to show an improvement towards the end of the first quarter and steadily increased until the production of steel in Sheffield expanded and was recently stated to be about 1000 tons per week higher than a year ago. The re-rollers in particular have been busy, some of them operating almost at capacity, whilst the engineering shops, owing to the large orders for chemical and other machinery, are well employed. The orders given out to the railways have entirely changed the situation in that department, which is busier than for years past.

Current Business.

It is announced that Scott's Shipbuilding and Engineering Company, Ltd., of Greenock, has secured an order for passenger and cargo motor ships for a London firm. The London and North-Eastern Railway Company's order for chairs has been distributed between firms at Nottingham, Blaydon-on-Tyne, Middlesbrough, Thornaby-on-Tees, and Alloa. The order was for about 4000 tons of cast iron permanent way chairs. The London, Midland and Scottish Railway Company have announced that their rolling stock programme for 1934 will include orders for 232 locomotives, 159 locomotive boilers, 674 carriages, and 5365 wagons. The total sum which will probably be spent by the L.M.S. upon improvements and renewals will amount to £8,400,000. This, with the programmes of the London and North-Eastern, the Great Western, and the Southern railway companies, will involve a total expenditure of £14,450,000. The Department of Overseas Trade announces that the following contracts are open for tender:—South African Railways and Harbours, supply and delivery of structural steel for an engine shed at Bramfontein (Johannesburg, January 8th); Egypt, Ramleh Electric Railway, Alexandria, garage equipment (Alexandria, January 15th); Southern Rhodesia, Municipality of Gwelo, steam-raising plant, including one water tube boiler with integral superheater, mechanical stoker, soot blowers, feed regulator, and all accessories, one induced draught plant, steam and feed piping with pumps (South Africa, February 6th); Municipality of Bulawayo, one 4000-kW turbo-alternator, switchgear, and transformers (Bulawayo, February 1st).

Copper and Tin.

Conditions in the year 1933 have not been very favourable for the non-ferrous metal markets. At times copper prices have shown a strong tendency to advance, but the financial situation in most markets and the exchange fluctuations which followed the departure of the United States from the gold standard has made business difficult and created a lack of confidence amongst consumers. At the end of the year, however, a sharp burst of buying occurred, some of which was undoubtedly of a speculative character, and prices advanced sharply, but as this movement followed a reaction in prices, the levels ruling at the close of the year were little above those in force a few weeks previously. The statistical position of the metal has certainly improved, largely owing to a vigorous curtailment of output. At the end of 1932 the stocks in the producers' hands were estimated at about 700,000 tons, and during the year these have been reduced to about 640,000 tons. . . . The gradual tightening of the control of the tin position by the International Pool has been the principal feature of the market during the past year. Early in 1933 it was stated that the International Pool held about 21,500 tons of tin, and for a time it seemed as though it would be some time before this accumulation was disposed of. The heavy buying, principally by America, but also by speculators on the Continent, which followed the abandonment of the gold standard by the United States, enabled a considerable quantity of this metal to be disposed of, and at the end of November it was stated that the total quantity in the hands of the Pool did not exceed 8000 tons. At one time during the year the American demand caused a drain upon the stocks in Great Britain, which was reflected in a considerable advance in prices, and at the end of December the price was below the highest touched during the American buying movement. As the quotation was £148 at the beginning of last January, the advance to a price of £227 at the close of the year must be considered a satisfactory movement. The year opens with sound prospects, since the statistical position appears to be steadily improving, and the industrial demand is reported to be expanding.

Lead and Spelter.

Although the position in the lead market has improved during the past year, its chief characteristic has been the steadiness of the quotations. At the beginning of the year the price was £10 15s., and although the quotation advanced at times to nearly £14, the year closed with the price at £11 7s. 6d. It is perhaps surprising that values did not appreciate to a greater extent, since during 1933 the consuming trades were busy and the demand for the raw material was in excess of anything known for several years. The activities of the cable makers were not much in evidence, owing to the completion of the grid scheme, but the manufacturers of lead pipes and sheets were working at high pressure, and the battery trades also absorbed considerable quantities of the metal. Stocks, however, were heavy, and perhaps the producers showed wisdom in keeping prices low, and thereby stimulating buying for industrial purposes. . . . The outlook for the spelter market at the commencement of 1933 was regarded favourably, as it was generally understood that consumption was in excess of production, and although heavy stocks existed in the makers' hands, it was believed that the comparatively low price of the metal—£14 17s. 6d.—would result in these being gradually disposed of. This position has ruled during the greater part of the year, and although prices have moved within a comparatively narrow margin, the highest point touched being just over £17, the market has always had a healthy appearance. The quotation at the close of the year was about £15, but the producers evidently regard the future with confidence, as the existing arrangements regarding production and quotas are to be continued until the end of June. At the end of November the stocks had dropped to 128,000 tons, or more than two months' supply. The weakest spot in this market during the whole of the year was the poor demand from the galvanising trades. On the other hand, the brass industries were actively employed during the latter part of 1933, and took considerable quantities of spelter. The Continental market also shows signs of improving towards the end of the year, so that the spelter market enters the New Year in a fairly satisfactory position.

Current Prices for Metals and Fuels.

Makers' official home trade prices, per ton, delivered buyers' stations. Sections, joists and plates are subject to a rebate to home users purchasing only from associated British Steelmakers: joists, 22s. 6d.; plates and sections, 15s. Export orders of 250 tons and over may be subject to special quotations.

French Engineering Notes.

(From our own Correspondent in Paris.)

Commercial Treaties.

The year closes with a general desire to save the industrial situation by re-opening foreign markets. This solution is not so obvious as it appears, in view of the policy that has been pursued all along of making the country self-supporting by monopolising the home market and developing colonial trade in the hope that manufacturers would be able to tide over the period of world economic adjustment. The danger of this attitude is revealed by the fact that the heavy contraction of exports has lessened the country's wealth and helped to check public and private enterprise. Since the Colonies are now recognised as being complementary to foreign markets and cannot be substituted for them, the position is in appearance aggravated. During the first eleven months of the year the value of manufactured goods sent to the Colonies was 3770 million francs out of an export total of 6772 millions, which means that colonial purchases have retrograded at the same time that foreign trade has fallen to a disquieting level. The imports of produce from the Colonies far exceeded those from other countries. It is therefore comprehensible that colonial interests should influence negotiations for commercial arrangements, which are further complicated by the high level of production costs in this country as compared with those elsewhere. It is clear that if commercial negotiations are to be carried to a successful issue some sacrifices must be made for the common good. They will necessarily be long and arduous. The negotiations with Germany for a new commercial treaty have broken down, partly through the desire of the French to reduce import quotas. Every effort will be made in the coming twelvemonth to carry through commercial negotiations, and there is fair promise that, if the financial situation is placed on a firm basis and facilities are offered for foreign exchanges, industrial activity will revive.

Railway Rolling Stock.

Where so much depends upon State expenditure the situation becomes precarious when, as at present, the State has to enforce a rigid policy of economy, and in all departments there are cuts that will affect engineering industries. The sum of 2500 million francs originally arranged to be spent on railway works during 1934 has been reduced by 500 millions. Of the amount allotted by the Superior Railway Council, 233 millions will be devoted to the construction of new lines, 498 millions are set apart for the purchase of rolling stock, and 319 millions for maintenance of locomotives and wagons, while 180 millions will be utilised for the construction of rail cars. Private builders complain that most of the orders for rolling stock will go to the railway companies' own works and that what is left for specialised firms will be wholly insufficient to provide them with even moderate employment. There are better prospects for rail makers in view of the reported intention of the railway companies to employ rails of 62 kilos. to the metre on all the heavy traffic lines. For some time past there has been a controversy over rail breakages, which were at first attributed to the running of heavy locomotives, though it is now affirmed that the trouble has been traced to defective wheel tires, which put abnormal stresses on the rails when braking.

Shipping.

A report issued by the Ministry of Merchant Marine on the situation of shipping at the beginning of 1933 shows that the number of ships at that date was 2419, representing a tonnage of 3,391,303, as compared with 2110 ships and 1,994,402 tons in 1914. The total tonnage of sailing ships fell during the same period from 561,373 to 92,586. There are sixteen shipyards with eighty-five stocks, of which seven can construct ships of between 180 m. and 250 m. long and one of more than 300 m. During the past year the situation of shipping was extremely critical, for at the beginning of January there were only eight ships on the stocks, representing a tonnage of 21,000, and on July 1st there were six vessels totalling 5000 tons. Nevertheless, shipbuilders are confident that the crisis is coming to an end and that a revival of international trade will bring orders to shipyards.

A Wilbur Wright Anniversary.

The town of Le Mans celebrated on Monday of last week the twenty-fifth anniversary of the first long-distance flight by Wilbur Wright, when he covered 99·8 kiloms. in 1 h. 54 min. after he had, a few hours previously, made another record by attaining the altitude of 115 m. He had begun his experiments on August 8th, 1908, on the racecourse near Le Mans, when the machine was launched from rails by a catapult. Wilbur Wright is said to have attached little importance to the aeroplane other than for military purposes, and he explained his preference for the catapult by saying that if the machine landed behind the lines of an enemy they would not be able to use it themselves. It was when passengers were carried, including the late Monsieur Paul Painlevé, that the commercial possibilities of the aeroplane were recognised. The initial flight on August 8th was the first that Wilbur Wright flew in public, for his experiments at Kitty Hawk had been carried out with great secrecy. It is interesting to recall that the Wright biplane had a width across the planes of 40ft. It had two propellers turning at 400 revolutions per minute and driven by a four-cylinder engine of 27 horse-power.

Rail and Road.

A significant step has been taken by the Minister of Public Works in transferring roads from the services that have hitherto controlled them to the State Railway Department, on the plea that the solution of the road problem can only be reached by reference to the conditions of railway working. Lorries are, says the Minister, auxiliaries of the railways and must connect up with them, and traffic on roads that follow or cross railways cannot be carried on except in conjunction with the railways.

British Patent Specifications.

When an invention is communicated from abroad the name and address of the communicator are printed in italics.

When an abridgment is not illustrated the Specification is without drawings.

Copies of Specifications may be obtained at the Patent Office Sale Branch, 25, Southampton-buildings, Chancery-lane, W.C., at 1s. each.

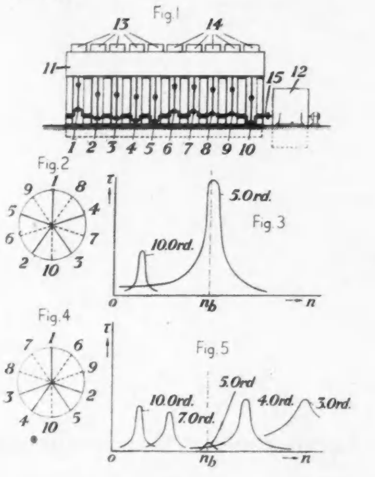
The date first given is the date of application; the second date, at the end of the abridgment, is the date of the acceptance of the complete Specification.

INTERNAL COMBUSTION ENGINES.

401,624. July 31st, 1933.—Ten-cylinder Engines, Sulzer Frères Société Anonyme, Winterthur, Switzerland.

The inventors aim to reduce the internal cyclic stresses in the crank shafts of ten-cylinder, two-stroke engines caused by the firing of the individual cylinders. The wording of the specification is devised to cover a certain arrangement of the cranks of one group of five in relation to the other five, but the essential idea is to destroy any resonance in the shaft with the usual arrangement, illustrated by Fig. 2, in which the engine is divided symmetrically, as regards the length of the crank shaft, in the sequence of firing, and large torsional oscillations of the fifth order are produced, as shown in Fig. 3. With the inventors' arrangement the firing impulses follow one another as indicated in Fig. 4, so that, in a way, the cylinders are out of step and the oscillations are reduced to those shown in Fig. 5.—*November 16th*, 1933.

Nº401,624

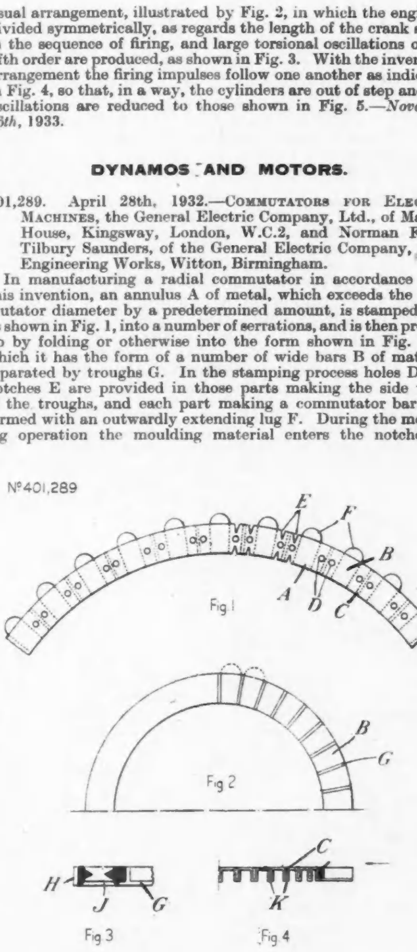


DYNAMOS AND MOTORS.

401,289. April 28th, 1932.—Commutators for Electric Machines, the General Electric Company, Ltd., of Magnet House, Kingsway, London, W.C.2, and Norman Frank Tilbury Saunders, of the General Electric Company, Ltd., Engineering Works, Witton, Birmingham.

In manufacturing a radial commutator in accordance with this invention, an annulus A of metal, which exceeds the commutator diameter by a predetermined amount, is stamped out, as shown in Fig. 1, into a number of serrations, and is then pressed up by folding or otherwise into the form shown in Fig. 2, in which it has the form of a number of wide bars B of material separated by troughs G. In the stamping process holes D and notches E are provided in those parts making the side walls of the troughs, and each part making a commutator bar B is formed with an outwardly extending lug F. During the moulding operation the moulding material enters the notches E or/and holes D, whereby the bars are strongly held in place. Adjacent limbs of neighbouring bars may be separated by mica, or the moulding material may be relied upon to insulate the segments from one another. During the moulding operation the ring A formed with corrugations is placed between and spaced from an inner supporting ring G and an outer strengthening ring H, Fig. 3. The moulding material is then moulded into the space between the rings and into the spaces between the limbs of the commutator bars. The inner ring G may form part of a spider and the rings may be flanged, notched, or formed with lugs, so that the insulating material is strongly held thereto. After the moulding material has formed a solid mass, the under surface J of the serrated disc is machined down until the metal forming the bottom walls K of the troughs is cut away, thus open-circuiting each commutator bar B.—*October 30th*, 1933.

Nº401,289

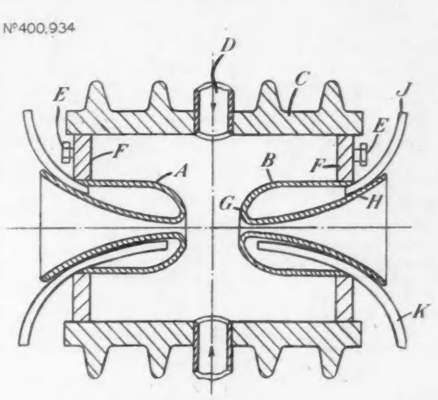


ELECTRICAL APPLIANCES.

400,934. February 23rd, 1932.—Conversion of Electric Currents, Dr. Ing. Erwin Marx, of Rankestrasse 3, Baunschweig, Germany.

Electrodes for a spark gap rectifier suitable for power circuits are described in this specification. The electrodes A and B are fitted into a pressure chamber C of insulating material. Compressed air or other gas is introduced at D and flows out through the nozzle-shaped orifices in the electrodes. E represent the line connection terminals on the plates F by which the electrodes are carried. If a flashover is provoked between A and B by a transient high voltage, ignition of the arc takes place between two closely opposing points of the electrodes, and immediately after ignition the arc, owing to the current of air, travels from the ignition point towards the wide nozzle outlet, viz., for instance, from point G to point H of the electrode B. Owing to the double-sided blow-out action, the arc is, in this case, lengthened to an unusual extent and ruptures with certainty when the current passes through zero, as when alternating current rectification is being performed. The re-establishment of the arc is prevented as there are no longer any free electrons present in the vicinity of the electrodes owing to the current of air. High-efficiency rectification can be obtained by this arrangement. Cooling fluid is supplied through the pipes J, K.—*October 23rd*, 1933.

Nº400,934

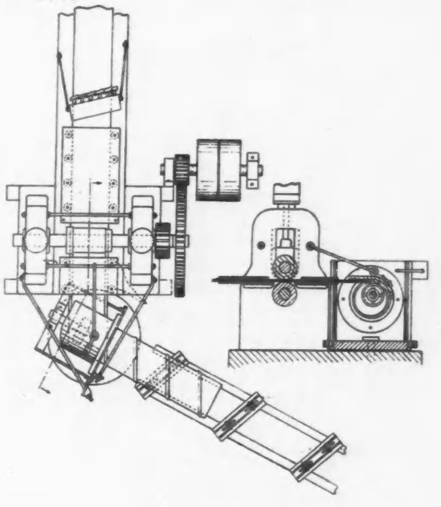


MACHINE TOOLS AND SHOP APPLIANCES.

401,139. January 30th, 1933.—Making Steel Pipes, A. G. H. Ferguson and M. J. Ferguson, Gordon-street, Footscray, Victoria, Australia.

Steel pipe is made, according to this invention, by pushing strip tangentially into a die to form a helix and then welding the joints. In passing through the feed rolls the edges of the strip are bent so that it wraps together with a spigot and socket effect. The making machine is illustrated by the drawings, but the welding apparatus is not shown. A feature of the system is the entrance portion of the die, which gives to the strip a sharper curvature than that necessary for the ultimate diameter of the pipe, so that the steel may recover from its elasticity without pressing unduly on the interior of the die.—*November 9th*, 1933.

Nº401,139

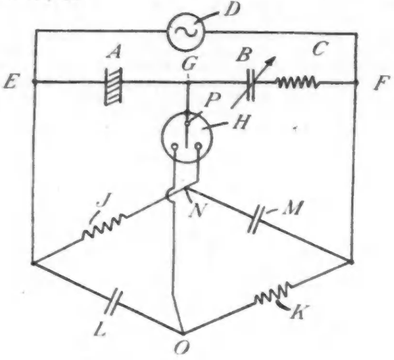


MEASURING AND TESTING INSTRUMENTS.

401,488. October 26th, 1932.—Electrical Measuring Circuits and Apparatus, the British Thomson-Houston Company, Ltd., Crown House, Aldwych, London, W.C.2, and George Rupert Ridpath Bray, of 86, Dunchurch-road, Rugby, and Kenneth James Rawcliffe Wilkinson, of 16, Vernon-avenue, Hillmorton Paddox, Rugby.

The apparatus described in this specification is particularly applicable to the measurement of power factor or loss angle of samples of insulating materials. An approximate measure of these values may be obtained very quickly where a high standard of accuracy is not required—for example, in manufacturing shop tests. The terminals of the condenser A made up with the sample dielectric are connected in series with a standard condenser B and resistance C, one or both of which may be variable. An alternating supply D is connected across the extreme terminals E F. If the power factors of the sample A and of the circuit comprising condenser B and C are equal, the potential differences between their junction G and their extreme terminals E and F will be in the same phase. To test this, a circuit comprising the symmetrical electrometer H is employed. A voltage for the fixed electrodes of this electrometer may be obtained by a bridge circuit made up of two resistances J, K, and two condensers L, M, all of equal impedance and connected as shown. The voltages at E N, E O, F N, F O will all be equal in amplitude. The fixed electrodes of the electrometer are connected across N O, and the correctness of the bridge may be checked by connecting the moving electrode P to E and to F in succession when there should be no deflection. If, then, P is connected to the junction G, and if the power factor of G F is adjusted by varying the capacity H and resistance C until the electrometer gives a central reading, then the potential differences at E G, G F, E F are in the same phase and the power factor of G F is the same as that of E G, or the sample A.—*November 16th*, 1933.

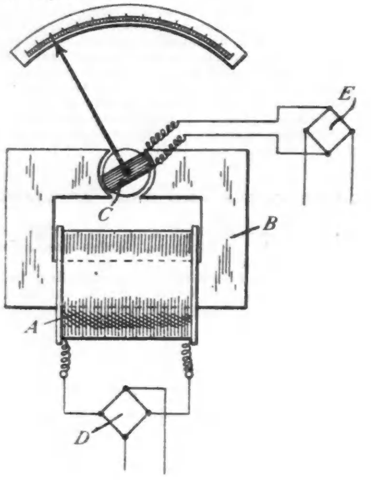
Nº401,488



401,277. May 7th, 1932.—Alternating Current Electrical Instruments, Elliott Brothers (London), Ltd., of Century Works, Lewisham, Kent, and George Frederick Shotter, of 14, The Ridgeway, Friern Barnet.

The instrument shown is for measuring volt ampères in a single-phase system. A is the voltage winding wound on a copper spool surrounding a magnetic core B of substantially horse-shoe form. A coil C is suspended or pivoted to move in the space between the poles. The voltage winding A is connected to rectifying apparatus D connected, in turn, across the supply, and similarly the coil C which constitutes a current coil is connected to rectifying apparatus E, which is connected in series with the supply. A polyphase instrument and a modification of the invention are also described.—*November 7th*, 1933.

Nº401,277

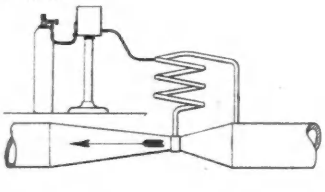


WATER PURIFICATION.

401,589. April 18th, 1933.—Chlorinating Apparatus, G. D. Peet, 11, Mill-street, Belleville, Essex County, New Jersey.

The inventor explains that in the sterilisation of water by means of chlorine there is the possibility of trouble through the production of chlorine hydrate if the added solution is of too strong a concentration. A pump is generally used to provide the water for making the solution, and, as a consequence, there is a tendency to reduce this flow as much as possible. The inventor, however, uses the pressure difference of a Venturi tube that requires no attendance to produce a copious auxiliary flow into which the chlorine gas is introduced.—*November 16th*, 1933.

Nº401,589



MISCELLANEOUS.

401,126. December 16th, 1932.—Lubricating Internal Combustion Engines, Tecalemit, Ltd., Great West-road, Brentford, Middlesex.

This invention is concerned with the addition of oil to the combustible mixture of internal combustion engines for lubricating purposes. An oil container A is attached to a fitting B on the induction pipe. This fitting has a restricting orifice C and two wicks D and E dipping into the oil. The excess pressure on the wick D at the inlet side is then transmitted to the wick E through the oil, thus adding a pressure effect to the capillary action, facilitating the flow of oil into the fuel pipe. The flow of oil will be proportional to the difference of pressure. It will also be noted that in accordance with the reduction of the quantity of oil in the reservoir, the viscosity of the mixture of oil and fuel will diminish, and that consequently the flow through the wick E will increase. Thus, the decrease of the amount of oil in the mixture drawn through the wick will be automatically compensated, whilst the proportion of oil with respect to the fuel in the pipe at the inlet side of the apparatus will remain constant.—*November 9th*, 1933.

[PRICE { WITH SUPPLEMENT } ONE SHILLING BY INLAND POST 1s. 3d.

PUBLIC NOTICES.

Borough of Reigate.
ELECTRICITY DEPARTMENT.
OFFERS are INVITED for the SALE by the Corporation of the following PLANT:—

Two 150 B.H.P. Three-cylinder Carels Diesel Engines, coupled direct to 2500-Volt Single-phase 50 Cycles E.C.C. Alternators and Exciters.

The plant can be inspected by appointment at the Corporation's Generating Station, Wray Common-road, Reigate.

Offers, endorsed "Tender for Plant," must be delivered to the Town Clerk, Municipal Buildings, Reigate, not later than Wednesday, the 10th January, 1934.

The highest or any Offer will not necessarily be accepted.

HEBER DAVIES,
Town Clerk.

Municipal Buildings, Reigate,
18th December, 1933. 1387

County Borough of Brighton.
WATERWORKS DEPARTMENT.
BALSDEAN SUPPLY.
TO MAIN-LAYING CONTRACTORS.
The Corporation are prepared to receive TENDERS for CARTING, LAYING and JOINTING about 4026 Yards of 20in., 360 Yards of 15in., and Short Lengths of 8in. and 3in. SPUN IRON PIPES, together with the necessary Valves and Specials.

Copies of the general conditions of contract, specification, bill of quantities, and form of Tender, may be obtained upon application to the Waterworks Engineer, Mr. A. B. Cathcart, M. Inst. C.E., M.I. Mech. E., 12, Bond-street, Brighton, and enclosing a cheque for Two Guineas, which will be refunded upon receipt of a bona fide Tender (not subsequently withdrawn), and the return of the documents. The drawings may also be inspected at the offices of the Waterworks Engineer, as above.

Sealed Tenders, endorsed "Tender for Pipe Laying: Balsdean Main," and addressed to me, must be delivered at my office at the Town Hall, Brighton, by Twelve Noon on Monday, 15th January, 1934.

JAS. H. ROTHWELL,
Town Clerk.

Town Hall, Brighton,
22nd December, 1933. 1386

Midhurst Rural District COUNCIL.
WATERWORKS.
CONTRACT No. 8.
TO CONTRACTORS.
The above Council are prepared to receive TENDERS for the COMPLETE EQUIPMENT of DUPLICATE ELECTRICALLY DRIVEN PUMPING PLANT, of British manufacture, to be installed over two bored wells at Easebourne Pumping Station.

The works included in the contract consist of Two Turbine Pumps, each driven by an electric motor, together with all necessary Electrical Equipment and Connections inside the building, in accordance with drawing, general conditions, and specification prepared by the engineers, Messrs. John Taylor and Sons, Caxton House, Westminster, S.W.1.

Copies of the specification, drawing, and form of Tender may be obtained from the offices of the Engineers upon payment of £5 (cheque only), which will be returned upon receipt of a bona fide Tender.

Sealed Tenders, endorsed "Pumping Plant, Contract No. 8," addressed to the undersigned, at his office at Midhurst, must be received before Noon on Monday, the 29th day of January, 1934.

The Council does not bind itself to accept the lowest or any Tender.

By Order,
(Signed) J. M. FURNEAUX,
Clerk to the Council.

Council Offices,
Midhurst,
Sussex. 1385

Metropolitan Borough of POPLAR.
ELECTRICITY UNDERTAKING.
APPOINTMENT OF CHIEF TECHNICAL ASSISTANT.
APPLICATIONS are INVITED from fully qualified persons not more than 36 years of age for the POSITION of CHIEF TECHNICAL ASSISTANT TO THE UNDERTAKING of the Council.

The salary payable will be at the rate of £800 per annum.

Applicants must be conversant with large Power Tariffs, System Change-overs, Organisation of Meter Test and Repair Departments. A knowledge of Scientific Street Lighting will be an advantage. It is essential that candidates be Corporate Members of the Institute of Electrical Engineers.

The person appointed will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Forms of application, with conditions of the appointment, may be obtained from my office upon receipt of a stamped, addressed foolscap envelope, and must be returned so as to reach me not later than 12 Noon on Friday, 19th January, 1934, endorsed "Chief Technical Assistant."

Canvassing, either directly or indirectly, will disqualify.

H. E. DENNIS,
Town Clerk.

Council Offices,
High-street,
Poplar, E.14,
December, 1933. 1393.

Wolverhampton Corporation
WATER UNDERTAKING.
DISTRIBUTION FOREMAN.
APPLICATIONS are INVITED for the POST of DISTRIBUTION FOREMAN at a salary, in accordance with the Corporation's Grading Scheme, of £200 per annum, rising by annual increments of £10 to £230 per annum, together with free house, coal and light, and uniform.

The successful applicant will be required to pass a medical examination, and to pay contributions to the Superannuation Fund.

Applicants must have had considerable experience in similar posts, including the Laying and Repairing of Large Water Mains and the Management of a Depot.

A stamped, addressed foolscap envelope should be sent to the undersigned for full details of the duties and conditions of employment, and a copy of the printed application form, and the applications on the said forms, accompanied by not less than two recent testimonials, must be returned not later than January 15th, 1934.

PUBLIC NOTICES.

City of Liverpool.
APPOINTMENT OF WATER ENGINEER.
The Corporation invite APPLICATIONS for the APPOINTMENT of WATER ENGINEER, at a salary of £1750 per annum, rising by annual increments of £50 to £2000 per annum.

The appointment will be subject to the Local Government and Other Officers' Superannuation Act, 1922, and the Standing Orders of the City Council, and will be determinable by three calendar months' notice on either side.

The person appointed will be required to reside within the city or such other place as may be approved by the Council, and to devote his whole time to the duties of the office, and will not be allowed to engage in private practice. He will be required to hand over to the City Treasurer any fees or other amounts received in connection with the appointment as provided by the Standing Orders of the Council. He will also be required to pass a medical examination.

Experience of impounding reservoirs is essential.

Particulars of duties may be obtained on application to the Town Clerk.

Applications, endorsed "Water Engineer," stating age, qualifications and experience, accompanied by copies of three recent testimonials, addressed to the Chairman of the Water Committee under cover to the Town Clerk, Municipal Buildings, Liverpool, must be delivered at the Town Clerk's Office not later than the 9th January, 1934.

Canvassing of members of the City Council, either directly or indirectly, will be considered a disqualification.

Dated this 12th day of December, 1933.

WALTER MOON,
Town Clerk.

Municipal Buildings,
Liverpool, 2. 1357

SITUATIONS OPEN.

CHIEF INSPECTOR REQUIRED for the Midlands, thoroughly accustomed to inspection of motor components, knowledge of latest practice, and accustomed to handling female labour.—Address, 1374, The Engineer Office. 1374 A

PUBLIC NOTICES.

Visiting Committee of the HERTFORDSHIRE COUNTY MENTAL HOSPITAL.
HILL END MENTAL HOSPITAL, NEAR ST. ALBANS, &c.

ENGINEER-IN-CHARGE.

The Visiting Committee of the Hertfordshire County Mental Hospital at Hill End invite APPLICATIONS for the APPOINTMENT of ENGINEER-IN-CHARGE of the Engineering Equipment (including Heating, Water, Sewage, and Electricity) at the Hill End Mental Hospital and the Cell Barnes Mental Deficiency Colony, near St. Albans.

Salary £450 per annum with unfurnished house valued at £50 per annum, such salary (over and above the first £150) for the present being subject to temporary deduction of 5 per centum.

The appointment will be subject to the provisions of the Asylums Officers' Superannuation Act, 1909, for which purpose the successful candidate will be required to pass a medical examination.

Successful applicants must be prepared to enter into an agreement if required.

Candidates must possess experience in the Management of Engineering Equipment in connection with Heating, Water, Sewage, Electricity, and in Repairs and Painting to Buildings, and Organisation and Control of Staff and Workmen, and be prepared to act as Clerk of the Works.

Applications, stating age (which must be between 33 and 40), qualifications, and experience must be submitted on the official form, which can be obtained from the Clerk to the Visiting Committee, Clerk of the Peace Office, Hertford, and must be returned duly completed not later than the Thirtieth day of January, 1934, accompanied by copies (not originals) of not more than three recent testimonials.

Selected applicants will be required to attend before a Committee at Hill End, St. Albans, and reasonable expenses in this connection will be paid.

ELTON LONGMORE,
Clerk to the Visiting Committee.

Clerk of the Peace Office,
Hertford,
23rd December, 1933. 1396

SITUATIONS OPEN.

COPIES OF TESTIMONIALS, NOT ORIGINALS, UNLESS SPECIFICALLY REQUESTED.

TO ADVERTISERS UNDER BOX NUMBERS IN THIS CLASSIFICATION.
For the benefit of applicants, the Proprietors are prepared to insert brief notices that vacancies are filled, upon receipt of notifications from the Advertisers. These notices (limited to one line) will be free of charge and co-operation is asked for.

ASSAM.—WANTED, for Tea Gardens, Qualified MECHANICAL ENGINEERS, with knowledge of Oil Engines, age 22-24. Must be of good education and well connected. Five years' agreement at monthly pay of £22 10s., rising to £31 17s. 6d., plus £3 a month horse allowance. Free passage, furnished bungalow, use of servants, medical attention. Offers permanent career with good prospects to right men.—Write, Box Z.B. 597, c/o Deacon's Advertising Agency, 5, St. Mary Axe, London, E.C.3. 1389 A

EXPERIENCED First-class DRAUGHTSMAN REQUIRED for old-established Firm of Mechanical Engineers in the North of England. Comprehensive knowledge of Railway Rolling Stock and Underframe Design essential. Locomotive experience desirable. Permanency for suitable and qualified man.
Address, fully stating training, qualifications, experience, age, and salary required, 1390, The Engineer Office. 1390 A

FOUNDRY RATEFIXER of First-class Ability REQUIRED in large works in Manchester district; possessed of thorough practical experience in Loam, Green and Dry Sand and Machine Moulding; must have had previous experience in Foundry Ratefixing, and be able to demonstrate ability to successfully Estimate Piecework Prices and Foundry Labour costs from drawings for all classes of general engineering. Age not exceeding 45. State fully previous experience and salary required. None without qualifications meeting the foregoing requirements should apply.—Address, 1383, The Engineer Office. 1383 A

THE Post You are Seeking May not be Advertised in this Column, but do not Lose the Opportunity of Bringing Your Requirements before all those who would be interested and could employ you. An Advertisement in the "Situations Wanted" Column would be seen by all Leading Engineering Concerns, for a cost of Four Lines 4s.; 1s. for each Additional Line. There is no better way of covering so large a field for such a small charge.

WANTED, Highly Technical Experienced LEADING DRAUGHTSMAN, up-to-date knowledge Hydraulic and General Engineering essential. Permanent situation for suitable man. Only those with first-class designing experience need apply—State age, experience, salary, &c., to HENRY BERRY and CO., Ltd., Croydon Works, Hunslet, Leeds, 10. 1392 A

DRAUGHTSMAN REQUIRED, with Knowledge of all classes of Gearing; good opening for right man.—Apply by letter, stating age, experience, and salary required, to ALFRED WISEMAN and CO. (1933), Ltd., Glover-street, Birmingham. 1397 A

DRAUGHTSMAN WANTED, with Experience in Designing Heavy Machine Tools, Gearing, and Millwork.—Applicants to state age, experience and salary required, to ref. "G.E.F.," BOULTON and PAUL, Ltd., Norwich. 1400 A

DRAUGHTSMAN WANTED, Experienced in Machine Tool and General Engineering. State age, experience, and salary required. Midland district.—Address, 1391, The Engineer Office. 1391 A

WELDING SUPERVISOR or FOREMAN REQUIRED, with technical and practical training. Accustomed to Welding various Metals, but chiefly Steel and Cast Iron; must be able to teach and supervise operators.—Address, stating age and experience in detail, also wages required, 1361, The Engineer Office. 1361 A

SITUATIONS WANTED.

CHARTERED ELECTRICAL ENGINEER, M.Eng. (Hons.), A.M.I.E.E., age 29, 3 yrs. apprentice, 4½ yrs. on the technical staffs of two leading manufacturers of electrical machinery. I am ANXIOUS to CHANGE for WORK with more scope and personal interest. Would be interested in small firm with a view to a partnership later.—Address, P4267, The Engineer Office. P4267 B

HEATING, VENTILATING and SANITARY ENGINEER. Highest qualifications, fully experienced, responsible designer, estimator and technician.—Address, P4269, The Engineer Office. P4269 B

IF the Man You are Seeking is not Amongst those Advertising in this Column, a Small Announcement in the "Situations Open" Column will Quickly and Economically Produce the Right Selection of Applicants, at the same time Eliminating Waste of Effort, Waste of Time, and Waste of Opportunity. The charge is Four Lines or under 4s., each Additional Line 1s.; Box numbers 6d. extra, which includes despatch of all replies.

MECHANICAL ENGINEER, with Good General experience and a good draughtsman, has own office and telephone, REQUIRES PART-TIME WORK.—Address, P1355, The Engineer Office. P1355 B

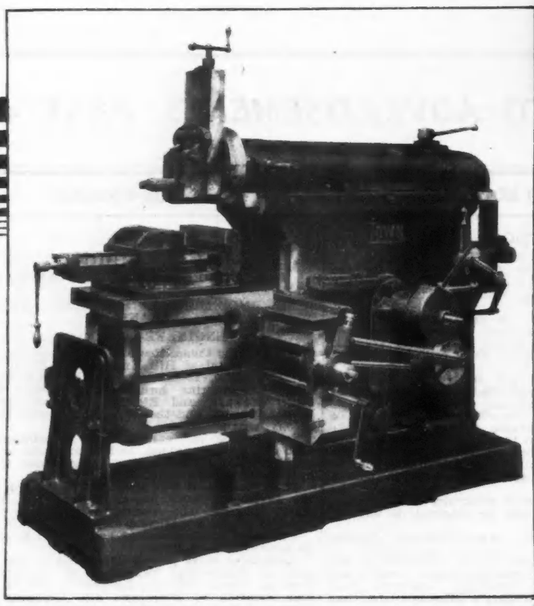
A great improvement in Shaper design



CENTRALISED CONTROL
CRANK TYPE
SHAPING MACHINES

The latest Town Shaping Machines embody many great improvements that make for increased productive capacity and lower machining costs. Amongst the many new interesting features are Centralised Control, Change Speed Gears mounted on 6 spline shafts, running in ball bearings. Main body casting with closed bottom forming oil container. Improved lubricating system. Pulleys arranged on opposite side to operator. Quick acting brake. All motions foolproof.

Built to the usual high Town standard of quality, these new Shaping Machines are designed to give long and lasting service. They represent remarkable value.

Enquiries are welcomed. Write for detailed specifications.

"SKATOSKALO"
ELECTRIC SCALING APPARATUS

At a large and important Power Station in the Midlands recently, a "Skatoskalo" Machine and two other makes were submitted to exhaustive tests on Stirling Boiler Tubes. Each machine underwent the same test under precisely the same conditions. Careful comparisons were made with regard to the removal of scale both from the straight and bent portions of the tubes. As a result the "Skatoskalo" machine was purchased.

Why not let us prove what a "Skatoskalo" machine will do for you—how it will reduce your fuel consumption and increase the efficiency of your steam raising plant generally? We will willingly give you a free demonstration at your own works.

FEEDER VOLTAGE REGULATION

7 POINTS IN FAVOUR OF THE MOVING COIL REGULATOR.

The Ferranti Moving Coil Regulator compares favourably with competitive equipment. Here are seven good reasons for using this method of voltage regulation,

1. Silent Operation.
2. Simple Control.
3. Short-circuit proof.
4. Supplied for any voltage.
5. Low losses.
6. Indoor, pole mounting or kiosk type.
7. Most lightly loaded mechanism.

A complete automatic unit of the street pillar type.

The Moving Coil Regulator eliminates voltage variation — the bane of the distribution engineer.

The Moving Coil Regulator is the simplest and most reliable means of assuring efficient electrical service, by maintaining constant voltage at your consumers' terminals.

HERBERT

A NEW LUMSDEN MOTOR-DRIVEN SURFACE GRINDER

THIS new Lumsden motor-driven Surface Grinder is ideal for high production in the machine shop or for the toolroom.

The roller-bearing spindle is so arranged that dropping of the spindle on intermittent work is positively prevented.

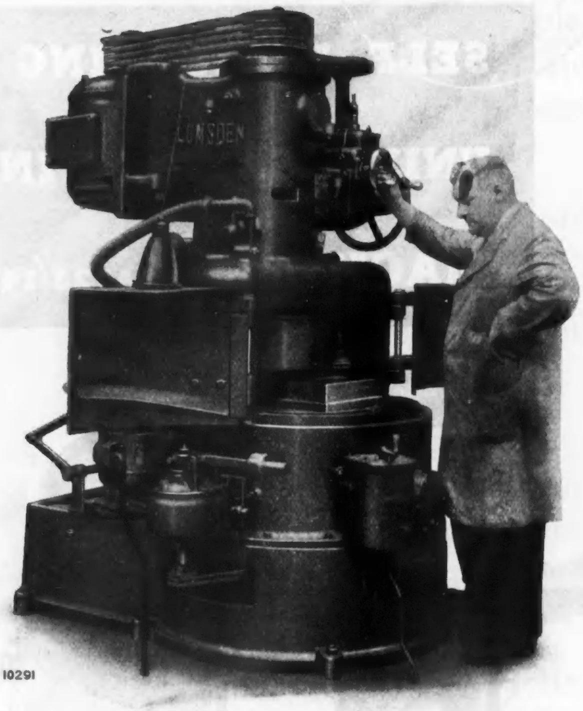
Ample power, rigidity and stability enable full advantage to be taken of the metal removing capabilities of the Segmental Grinding Wheel.

Machining allowances can be considerably reduced on the work, as the wheel is unaffected by scale; this results in a good saving of metal.

Our specialist will gladly give production figures for specified work.

Machines may be seen in operation in our own plant.

IMMEDIATE DELIVERY.



Lumsden No. 90LM. Segmental Wheel Surface Grinder with rotary table, operating on die blocks.

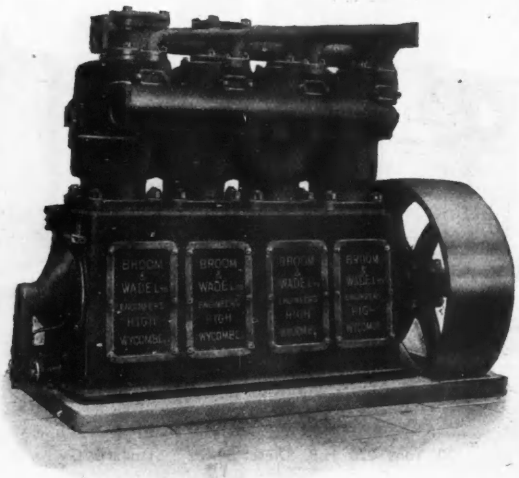
CATALOGUE ON REQUEST.

ALFRED HERBERT LTD. COVENTRY.

"BROOMWADE"

AIR COMPRESSORS

RECIPROCATING OR ROTARY, STATIONARY OR PORTABLE—ANY CAPACITY, PRESSURE OR DRIVE———A RANGE OF PLANTS WHICH, FOR **HIGH EFFICIENCY, LASTING RELIABILITY** AND **GENERAL EXCELLENCE,** ARE RENOWNED THROUGHOUT THE WORLD.

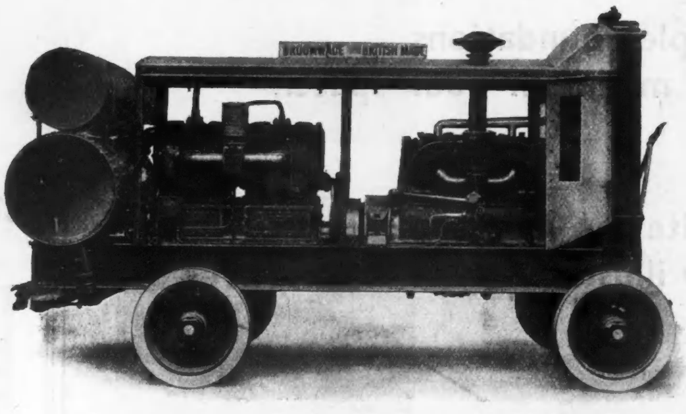


4 CYLINDER 10" × 12" COMPRESSOR. CAPACITY 600 CUB. FT. FREE AIR ACTUALLY DELIVERED PER MIN.

"BROOMWADE" COMPRESSORS EMBODY THE RESULT OF MORE THAN 30 YEARS' SPECIALISED EXPERIENCE, AND EMBODY OUTSTANDING FEATURES OF DESIGN WHICH ENSURE A LONG LIFE OF MAXIMUM SERVICE WITH A MINIMUM OF SUPERVISION AND EXPENSE.

WE SOLICIT YOUR ENQUIRIES.

FULLY DESCRIPTIVE LITERATURE GLADLY SENT UPON REQUEST.



PORTABLE SLEEVE-VALVE COMPRESSORS, EITHER PETROL, PARAFFIN OR DIESEL ENGINE DRIVEN. PLANT ILLUSTRATED ACTUALLY DELIVERS 340 CUB. FT. PER MINUTE.

HERBERT

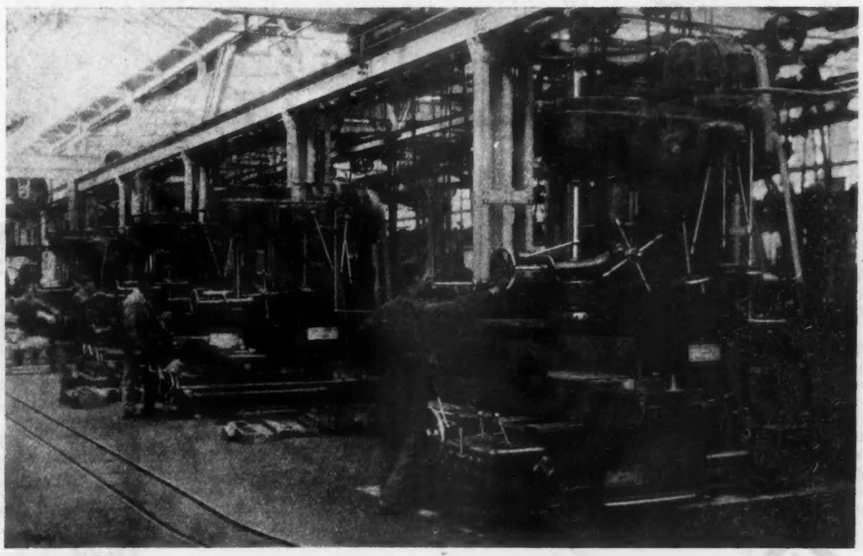
COMPLETE MILLING EQUIPMENT FOR IMMEDIATE DELIVERY.

THE full range of Herbert Milling Machines has been re-designed to meet the more exacting demands of modern production.

They are fitted with roller-bearing spindles; they have the necessary rigidity and stability to transmit enormous power to the cutter so that heavy cuts can be taken at high speeds and fast feeds.

We can supply complete equipment of machines, cutters — high-speed and Ardoloy tipped, cutter grinders, Norton Grinding Wheels and other accessories for immediate production.

200 Herbert Milling Machines may be seen in operation in our works.



A view in the Heavy Milling Department in our works.

HERBERT VERTICAL AND HORIZONTAL MILLING MACHINES ARE MADE IN 20 TYPES AND SIZES RANGING FROM 7″ × 3¾″ × 7″ up to 72″ × 33″ × 29″.

PROMPT DELIVERY.

ALFRED HERBERT LTD. COVENTRY.

HEATING...

What UNIVECTAIRS will do

1. Provide the most modern and efficient method of factory or workshop heating known. Complete installation at high level with the heat under directional control. No obstruction to production plant layout.
2. Provide a warm air blanket over cold doorways, loading bays or other cold spots.
3. Univectairs can readily be connected to existing steam or hot water installations to improve the effective heating value.
4. Connected to inlet ducts, Univectairs will bring in fresh air from outside and pass it into the factory warmed to the correct temperature.
5. Prevent air stagnation and fatigue by keeping the air content in constant circulation.
6. In addition, Univectairs will speed up industrial drying processes or disperse steam fog by providing an easily applied volume of moving warm air at the point where it is required.

Your production will definitely benefit if you instal . . . .

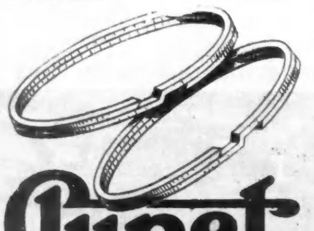
PUT BACK THE PULL
in your engines
with
THE



Clupet
PATENT
CURE

When engines start to lose power . . . run hot . . . "eat" oil—that's the time to fit Clupet Piston Rings.

Only Clupets have the "double-coil" that adjusts itself to worn cylinders without undue wear on the cylinder walls. They form a *perfect compression seal,* thus saving fuel and increasing efficiency. They cost only a little more than the ordinary ring with its short life, and are made in sizes to fit all engines, Gas, Petrol, Steam, Diesel, or Compressors. Give *your* engines the benefit of Clupets!

"F" VALVES

RESULTS *prove all our claims!*

IN 1923 when we introduced the "F" Type Renewable Seated Wheel Valve we claimed that it was the most reliable and economical Valve made and that it would give long and efficient service, even under the severest working conditions.

Since that time it has been proved conclusively that the "F" Type Valve is all that we claim.

Fitted with Nickloy Valves and Seats and Stainless Steel Spindles, "F" Valves are made in Bronze in all types and also Forged Steel for highly superheated steam.

If you are not already using "F" Valves—write us for full details and prices.

QUICKER PRODUCTION..

LOWER COSTS!

Electric welding of Torque Tubes, Back Axles, Brake Cross Shafts, Cross Members, and similar parts of cars results in immediate economy. The average output of B.I. Welders is OVER 60 WELDS PER HOUR. This method obviates boring, turning, drilling, pinning and brazing and one welding machine saves the use of three other machine tools, thus less floor space, less power and fewer machines are required when welded joints are made.

COST OF WELDED JOINT.........................1d.

COST OF BRAZED AND PINNED JOINT depends upon dimensions, say 6d.

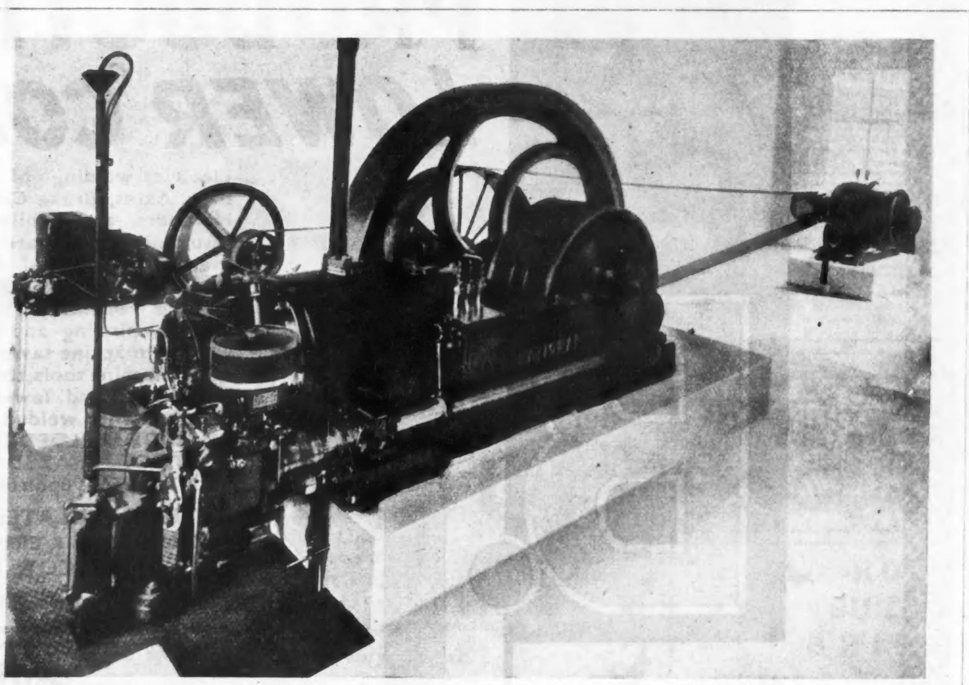
"WE HAVE BEEN INSTALLING NATIONAL ENGINES IN OUR PICTURE HOUSES FOR OVER 20 YEARS."



50 B.H.P. National Heavy Oil Engine, at the New Princess Picture House, Belfast.

Mr. J. Y. Moore, Managing Director, Alhambra Theatres, Ltd., 79, Donegall St., Belfast, writes :

"The 50 H.P. Heavy Oil Engine which you supplied to The New Princess Picture House, Belfast, is continuing to give us every satisfaction. OUR COST OF RUNNING PER WEEK OF 45 HOURS, INCLUDING LUBRICATING OIL, AVERAGES ABOUT 30/-. If we were paying the Corporation price of 3d. per unit for the same current produced by the engine our weekly cost would be about £10.

"THE ATTENTION IS PRACTICALLY NIL. THE OPERATOR SIMPLY STARTS THE ENGINE UP, LOCKS THE ENGINE ROOM DOOR AND GOES AHEAD WITH HIS OPERATING IN THE BOX. After each show is over he pays a visit to the engine room to see that the oiling system is correct, and carries on.

"We may say that we put this engine in after having previous experience of your 42 H.P. Heavy Oil Engine at our Lisburn Theatre. We have since installed a further 42 H.P. National Oil Engine at our Larne Theatre.

"We cannot speak too highly of the efficiency, reliability and economy of your engine, but this is only what we would expect from a National job, as WE HAVE BEEN INSTALLING NATIONAL ENGINES IN OUR VARIOUS PICTURE HOUSES FOR OVER TWENTY YEARS.

"Although National may cost slightly more to purchase, yet, when reliability is the first essential, the extra price is well invested money."

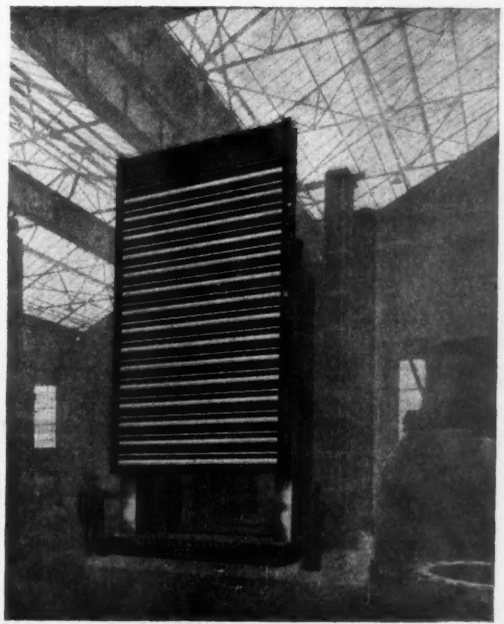
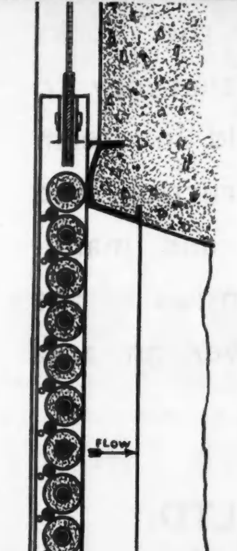
EMERGENCY ROLLING GATES

for

HYDRO - ELECTRIC TUNNEL INLETS





REMARKABLE ease of operation combined with great strength are outstanding features of the Glenfield Patent Free Rolling Gate for emergency closing of Hydro-Electric culverts or Water Turbine Inlets.

This type of gate has been developed by us, during recent years, for Hydro-electric service, and no ordinary sluice gate can meet the exceptionally severe conditions which it is designed to fulfil.

The whole of the gate structure acts as an anti-friction device, and the gate will close with certainty under its own weight, even with free discharge conditions and irrespective of the pressure head. It can also be raised by its own gear against the full unbalanced head, no by-pass of any description being required.

We shall be glad to forward, on request, an illustrated pamphlet describing these Gates.

ELIMINATING TROUBLE

VERY great reliance can be placed on Staybrite Castings made in the Firth-Brown Foundries in Sheffield.

Their very high resistance to corroding media, freedom from hard spots and ready machinability is due to that wealth of experience that only Firth's possess in the technique of Stainless Steel production.

Castings are available in one or other of the Firth Staybrite family of super rust-resisting and heat-resisting steels, for all purposes where acids or other chemicals, sea water and damp atmospheres would destroy less resistant metals.

Considerable economies can often be made by consultation with this Company on the subject of which Staybrite Steel to use for any particular purpose, and as to methods of machining, polishing and finishing of Firth Staybrite Castings.

ASHWORTH, SON & Co., Ltd., Midland Iron Works, DEWSBURY, England

Numbers of units as illustrated have been supplied for ventilating Engine Rooms and Holds of Ships; In-bye Ventilation of Mines; Air Circulation in Refrigerating Chambers ashore and aboard ship. Each unit consists of a special form of "Blackman" Streamline Fan housed in a heavy gauge sheet steel tube. Its construction ensures high efficiency in movement of air against high resistances, and reversibility of air-flow is obtainable also at high efficiency. This combination can be connected directly in a pipe trunk system. It is also suitable for Forced Draught on Land and Marine Boilers, and particularly for work of the order of 2 to 3 inches W.G. under commercially quiet conditions.

Full particulars and prices on request.

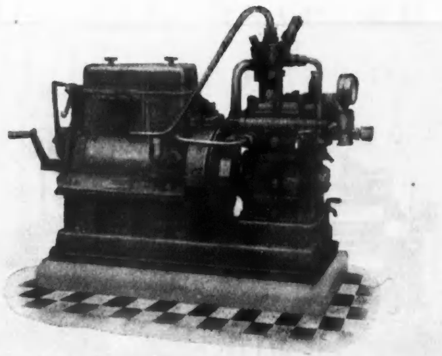
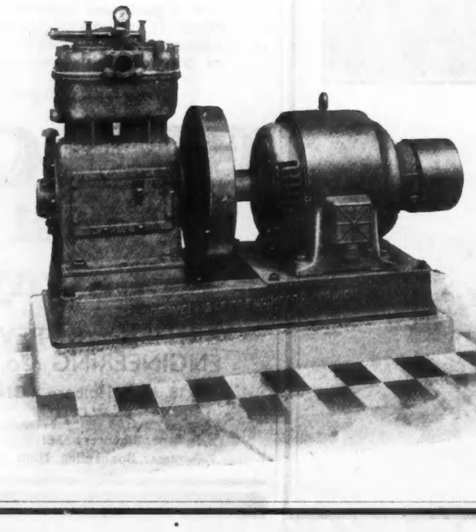
Two-stage compressors, similar to that illustrated on the right, are made in two types for pressures up to 450 and 1,000 lbs. per square inch respectively. These compact and rugged machines are driven by belt, petrol or Diesel engines or by electric motors.





Single-stage machines of the type shown on the left are suitable for capacities up to 300 cubic feet of free air per minute and pressures up to 100 lbs. per square inch. They are made with one, two and three cylinders and are driven in the same way as the machines above. They are also used as vacuum pumps.

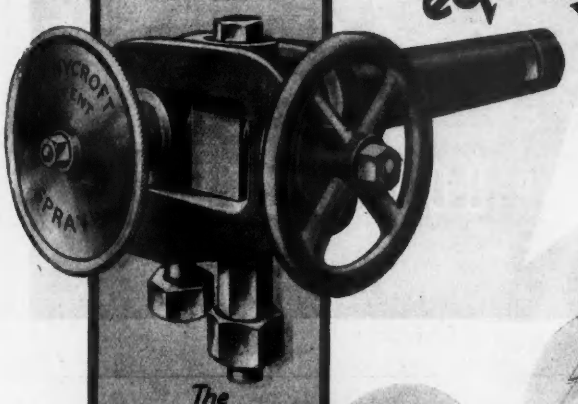
Valves are made at Sentinel Valve Works, Worcester.

17 VESSELS of the BLUE STAR LINE are equipped with THORNYCROFT OIL FUEL GEAR



The Thornycroft patent Oil Fuel Sprayer

Note how both edges of exit holes are tangential to the whirling chamber.

Long experience has proved the simplicity and many advantages of Thornycroft Oil Fuel Gear. Heated oil is sprayed into the furnace under pressure, and the correct mixture of fuel and air to ensure perfect combustion is assured by special patent burners and air cones, without the aid of steam. Complete pulverisation of the oil is effected in the sprayer by both edges of the exit holes being tangential to the whirling chamber. Thornycroft Oil Fuel Gear can easily be fitted to existing boilers and is suitable for all types of steam-raising units. Further particulars obtainable from:

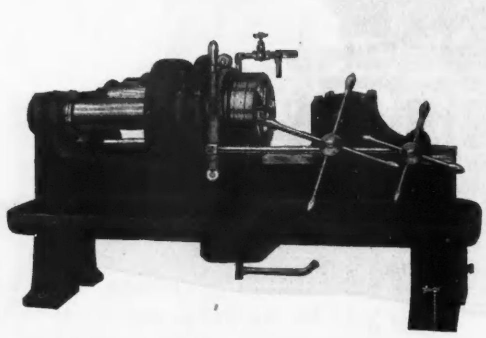
Heap's Patent Screwing Machines
(Registered Trade Mark)
with Tangential Dies.

Dies with Ground Threads for Precision work.



They are designed from beginning to end as high-class Machine Tools and embody features not found in any other make of Screwing Machine.

The Die Head is of our own Patented design.

All parts of the Head and also of the Die Holders which are liable to wear are of Hardened Steel.

The wall of metal which surrounds the Die Holders solidly supports them, and also eliminates the danger of the Operator being caught by protruding Die Holders.

The four-throw Cam is fitted with Hardened Steel Strips.

The Hardened Steel Contact Blocks of the Die Holders bear for their full width on the Cams.

These features render the Die Head when closed as rigid as a solid Die, and enable us to guarantee the Heads to screw perfectly parallel and uniform threads.

Catalogue free on request.

CENTRARD
NITROGEN HARDENED
Castings
Centrifugally & sand cast

A
CENTRICAST
PRODUCT

Centrard is a special alloy cast iron ideally suitable for components subject to wear. It is readily machinable and capable of surface hardening by the nitrarding process. The case provided has a Brinell figure of over 900, and a depth up to ·020".

Ultimate breaking strength 25 to 30 tons per sq. inch.

● Our plant is now equipped for the production of articles in Centrard, both by our well-known Centrifugal process and by ordinary sand-casting methods.

INDIVIDUALITY
IN THE CONSTRUCTION OF PIPE UNIONS.

The Jefferson Union Co., Lexington, Mass., U.S.A.

"JEFFERSON" Unions are different in design and performance from any others.
They contain all the required features sought for in the Perfect Union.
Malleable Iron Body with Hexagon ends, forming a sturdy housing for the brass seat and giving good grip for wrench.
Brass seating forced into a recess (away from corrosive action of fluid) under great pressure. Iron lip thus formed is spun over, making the seat immovable for all time.
Ground ball joint gives a perfect connection, no matter how often disconnected, and ensures a tight joint even with pipes out of line.
Tested and Guaranteed for all pressures up to 300 lbs. per sq. inch.
—— THAT IS **"JEFFERSON"** QUALITY.
For medium pressures up to 200 lbs., the **"OXFORD"** union is unsurpassed. It has all the "Jefferson" features, but is built lighter.

WELDABILITY

For certain types of work in a large variety of trades Workington Bessemer Acid Steel has ever been recognised as possessing clearly defined merits, amongst which is an acknowledged superiority for butt welding.

Makers of steel tubes will find in Workington Bessemer Acid Steel a material which is consistently uniform. Throughout the course of its manufacture there is complete control, for not only does Workington operate the only Bessemer Acid Steel plant in the British Isles but also it mines its own particularly rich and pure Cumberland Hematite ore, obtains coal and coke from its own pits and coke ovens, and limestone from its own quarries.

The works are in a most favourable position to handle sea-wise traffic at very low transport charges.

CONVEYOR BELTING

THE varied conditions under which conveyor belts operate, together with the class of material or merchandise they have to carry, make it practically impossible for us to standardise their manufacture. The fullest possible details therefore should be supplied to enable us to manufacture a belt in particular accordance to the operating conditions, and to ensure maximum efficiency and service.

Reddaway Conveyor Belts, both India Rubber and Textile, have a world-wide reputation for Reliability and Efficiency.

MISCELLANEOUS.

IMPORTANT NOTICE.

ALTERATIONS IN EXAMINATION SYLLABUSES.

The syllabuses of the A.M.I.C.E., A.M.I. Mech. E., and I.E.E. Examinations have recently been altered in important respects and prospective candidates are advised to make themselves thoroughly familiar with the changes.

Those candidates who are studying under the guidance of the BRITISH INSTITUTE OF ENGINEERING TECHNOLOGY are informed that the necessary modifications and additions will be made to their Programmes of Studies without extra charge.

The new edition of our General Prospectuses gives full particulars of the changes referred to. You should secure a copy of this Handbook without delay. It contains 256 pages of most useful information on Technical Examinations and Technical Home Study Courses.

Our new courses in Stationary and High-Speed Diesel Engines are proving extremely popular.

A postcard will bring our Prospectus to you—Free and Post Free.
